TABLE OF CONTENTS

IMPORTANT SAFETY CONSIDERATIONS
You must consider the possible negative effects of power, wiring, component, sensor, or software failure in the design of any type of control or monitoring system. This is very important where property loss or human life is involved. It is important that you perform satisfactory overall system design and it is agreed between you and Acromag, that this is your responsibility.

The information of this manual may change without notice. Acromag makes no warranty of any kind with regard to this material, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose. Further, Acromag assumes no responsibility for any errors that may appear in this manual and makes no commitment to update, or keep current, the information contained in this manual. No part of this manual may be copied or reproduced in any form without the prior written consent of Acromag, Inc.

1.0 GENERAL INFORMATION

The re-configurable XMC-VLX modules use the Xilinx Virtex-5 LX FPGA. Re-configuration of the FPGA is possible via a direct download into the Xilinx FPGA over the PCIe bus. In addition, on board flash memory can be loaded with FPGA configuration data for automatic Xilinx configuration on power-up. Flash programming is also implemented over the PCIe bus.

The example design includes an interface to the user rear I/O and front I/O connectors and an example memory interface controller to the 32M x 32-bit DDR-SDRAM. The example design also, includes an interface to the SRAM with DMA hardware support.

Table 1.1: *The XMC-VLX boards are available in both standard and extended temperature ranges*

1. The standard model includes 1Meg x 64-bit dual port SRAM.

MODEL	FPGA	OPERATING TEMPERATURE RANGE
XMC-VLX85	XC5VLX85T	0°C to +70°C
XMC-VLX85E	XC5VLX85T	-40°C to +85°C
XMC-VLX110	XC5VLX110T	0°C to +70°C
XMC-VLX110E	XC5VLX110T	-40°C to +85°C
XMC-VLX155	XC5VLX155T	0°C to +70°C
XMC-VLX155E	XC5VLX155T	-40°C to +85°C

KEY FEATURES

- **Reconfigurable Xilinx FPGA** – In system configuration of the FPGA is performed through a flash configuration device or via the PCIe bus. This provides a means for creating custom user defined designs.
- **32M x 32 DDR-SDRAM –** A 32M x 32-bit double data rate (DDR2) dynamic random-access memory (DRAM) is directly accessed through the Xilinx user-programmable FPGA. Read and write accesses to the DDR2-SDRAM are burst oriented.
- **1Meg x 64 Dual-Port SRAM –** A 1Meg x 64-bit dual-port static random access memory (SRAM) is included. One port of the SRAM provides a direct link from the PCIe bus to the SRAM memory. The second port of the SRAM provides a direct link to the Xilinx user programmable FPGA.
- **Interface to Front Multifunction Modules –** Various mezzanine modules ("AXM" model prefex), ordered separately, allow the user to select the Front I/O required for their application.
- **Interface to Rear P4 Connector –** The Virtex 5 FPGA is directly connected to 64 pins of the rear P4 connector. All 2.5volt IO standards supported by the Virtex 5 device are available. The example design provides low voltage differential signaling as 32 LVDS input/output signals.

PCIe INTERFACE FEATURES

- **Write Disable Jumper –** User configurable flash memory can be hardware write disabled by removal of an on board zero ohm surface mount resistor.

- **Example Design Provided –** The example VHDL design includes implementation of the Local bus interface, control of digital front and rear I/O, SRAM read/write interface logic, and DDR2-SDRAM memory interface controller.

- **PCIe Bus -** A four lane PCI Express 1.1 operating at a bus speed of 2.5 Gbps per lane per direction is provided. This gives up to 2GBytes/sec data rate on the bus.

- **PCIe Bus Master –** The PCIe interface logic becomes the bus master to perform DMA transfers.

- **DMA Operation –** The PCIe bus interface supports two independent DMA channels capable of transferring data to and from the on board SRAM. The example design implements DMA block and demand modes of operation.

- **64, 32, 16, 8-bit I/O** - Register Read/Write is performed through data transfer cycles in the PCIe memory space. All registers can be accessed via 32, 16, or 8-bit data transfers. Access to Dual Port Memory can be accessed via 64, or 32-bit transfers.

- **Compatibility** – Complies with PCIe Base Specification Revision 1.1. Provides one multifunction interrupt. The XMC-VLX is compatible with XMC VITA 42.3 specification for P15.

ENGINEERING DESIGN KIT

Acromag provides an engineering design kit for the VLX boards (sold separately), a "must buy" for first time VLX module purchasers. The design kit (model XMC-VLX-EDK) provides the user with the basic information required to develop a custom FPGA program for download to the Xilinx user-programmable FPGA. The design kit includes a CD containing: schematics, parts list, part location drawing, example VHDL source, and other utility files. The VLX modules are intended for users fluent in the use of Xilinx FPGA design tools.

BOARD DLL CONTROL SOFTWARE

Acromag provides a software product (sold separately) to facilitate the development of Windows (2000/XP/Vista/7®) applications accessing Acromag PMC and XMC I/O board products, PCI and PCIe I/O Cards, and CompactPCI I/O Cards. This software (Model PCISW-API-WIN) consists of low-level drivers and Windows 32 Dynamic Link Libraries (DLLs) that are compatible with a number of programming environments including Visual C++™, Visual Basic .NET® and others. The DLL functions provide a high-level interface to boards eliminating the need to perform low-level reads/writes of registers, and the writing of interrupt handlers.

BOARD VxWORKS SOFTWARE

Acromag provides a software product (sold separately) consisting of board VxWorks® software. This software (Model PMCSW-API-VXW) is composed of VxWorks® (real time operating system) libraries for all Acromag PMC and XMC I/O board products, PCI and PCIe I/O Cards, and CompactPCI I/O Cards. The software is implemented as a library of "C" functions which link with existing user code to make possible simple control of all Acromag PCI and PCIe boards.

BOARD QNX SOFTWARE

Acromag provides a software product (sold separately) consisting of board QNX® software. This software (Model PMCSW-API-QNX) is composed of QNX® (real time operating system) libraries for all Acromag PMC and XMC I/O board products, PCI and PCIe I/O cards, and CompactPCI I/O cards. The software supports X86 PCI bus only and is implemented as library of "C" functions which link with existing user code to make possible simple control of all Acromag PCI and PCIe boards.

BOARD Linux SOFTWARE

Acromag provides a software product consisting of board Linux® software. This software (Model PMCSW-API-LNX) is composed of Linux® libraries for all Acromag PMC and XMC I/O board products, PCI and PCIe I/O cards, and CompactPCI I/O cards. The software supports X86 PCI bus only and is implemented as library of "C" functions which link with existing user code to make possible simple control of all Acromag PCI and PCIe boards.

2.0 PREPARATION FOR USE

UNPACKING AND INSPECTION

Upon receipt of this product, inspect the shipping carton for evidence of mishandling during transit. If the shipping carton is badly damaged or water stained, request that the carrier's agent be present when the carton is opened. If the carrier's agent is absent when the carton is opened and the contents of the carton are damaged, keep the carton and packing material for the agent's inspection.

For repairs to a product damaged in shipment, refer to the Acromag Service Policy to obtain return instructions. It is suggested that salvageable shipping cartons and packing material be saved for future use in the event the product must be shipped.

This board is physically protected with packing material and electrically protected with an anti-static bag during shipment. However, it is recommended that the board be visually inspected for evidence of mishandling prior to applying power.

WARNING: This board utilizes static sensitive components and should only be handled at a static-safe workstation.

CARD CAGE CONSIDERATIONS

Refer to the specifications for loading and power requirements. Be sure that the system power supplies are able to accommodate the power requirements of the system boards, plus the installed Acromag board, within the voltage tolerances specified.

In an air cooled assembly, adequate air circulation must be provided to prevent a temperature rise above the maximum operating temperature and to prolong the life of the electronics. If the installation is in an industrial environment and the board is exposed to environmental air, careful consideration should be given to air-filtering.

IMPORTANT: *Adequate air circulation or conduction cooling must be provided to prevent a temperature rise above the maximum operating temperature.*

In a conduction cooled assembly, adequate thermal conduction must be provided to prevent a temperature rise above the maximum operating temperature.

BOARD CONFIGURATION

Remove power from the system before installing board, cables, termination panels, and field wiring.

Default Hardware Configuration

The board may be configured differently, depending on the application. When the board is shipped from the factory, it is configured as follows:

- The on board flash memory device is read/write enabled.
- The default configuration of the programmable software control register bits at power-up are described in section 3.
- The control registers must be programmed to the desired configuration before starting data input or output operation.

Front Panel Field I/O Connector

The front panel connector provides the field I/O interface connections via optional mezzanine I/O modules, purchased separately.

Rear P4 Field I/O Connector

The rear I/O P4 connector connects directly to the user-programmable FPGA. The VCCO pins are powered by 2.5 volts and thus will support the 2.5 volt IOStandards. The IOSTANDARD attribute can be set in the user constraints file (UCF). For example, rear I/O can be defined for LVCMOS25 (low voltage CMOS). The example design defines the rear I/O to LVDS_25 (Low-Voltage Differential Signaling) in the user constraints file. The 2.5 volt IOStandards available are listed in table 6-39 of the Virtex 5 User Guide available from Xilinx.

The example design defines the rear I/O connector with 32 LVDS I/O pairs. The LVDS pairs are arranged in the same row in table 2.1. For example, RIO0_P and RIO0_N form a signal pair. The P identifies the Positive input while the N identifies the Negative input.

Table 2.1: *Board Rear Field I/O Pin Connections*

The example design implements 2.5volt LVDS I/O to the rear connector. Signal pairs are routed to pins (1,3), (2,4) etc.

Ch.	Positive Pin Description	Pin	Negative Pin Description	Pin
0	RIO0_P	1	RIO0_N	3
1	RIO1_P	2	RIO1_N	4
2	RIO2_P	5	RIO2_N	7
3	RIO3_P	6	RIO3_N	8

27	RIO27_P	54	RIO27_N	56
28	RIO28_P	57	RIO28_N	59
29	RIO29_P	58	RIO29_N	60
30	RIO30_P	61	RIO30_N	63
31	RIO31_P	62	RIO31_N	64

This connector is a 64-pin female receptacle header (AMP 120527-1 or equivalent) which mates to the male connector on the carrier/CPU board (AMP 120521-1 or equivalent).

Non-Isolation Considerations

The board is non-isolated, since there is electrical continuity between the logic and field I/O grounds. As such, the field I/O connections are not isolated from the system. Care should be taken in designing installations without isolation to avoid noise pickup and ground loops caused by multiple ground connections.

Standalone Operation

Powering the XMC-VLX as an independent board is possible using the J7 and J8 board through holes. As an independent standalone board the

XMC- VLX board would not be plugged into a PCIe slot. To independently power the board, the required +12, VPWR5/12 volt, and +3.3 volt power supplies and the return GND must be provided via the J7 and J8 contact holes. The holes have 29 mil openings with 60 mil pads. The location of the contact holes on the board are shown in diagram at the end of this manual.

Flash Write Disable Resistor

By default the flash memory (U6) is read/write enabled. Removal of resistor R172 disables writing the flash configuration device. Refer to Resistor Location Drawing at the end of this manual to identify the board location of R172.

3.0 PROGRAMMING INFORMATION

This Section provides the specific information necessary to program and operate the board.

GETTING STARTED

1. The XMC VLX board is shipped with the user-programmable Xilinx FPGA code stored in flash memory. Upon power-up the XMC VLX will automatically configure the FPGA with the example design code stored in flash. As a first step become familiar with the XMC VLX, as supplied by Acromag. The board will perform all the functions of the example design.

   The Example Design Memory Map section gives a description of the I/O operations performed by the example design. It will allow testing of digital I/O, interrupts, read/write of dual port SRAM, read/write of double data rate SDRAM, and testing of both DMA channels. It is strongly recommended that you become familiar with the board features by using the example design as provided by Acromag.

   Do not attempt to reconfigure the flash memory until after you have tested and become familiar with the XMC VLX as provided in the example design.

2. After you are familiar with the XMC VLX and have tested it using the example design, you can move on to step 2. Here you will modify the example design VHDL code slightly. It is recommended that you test this modified example design using the reconfiguration direct method. It is not recommended that the flash be overwritten until you have tested your code. The reconfigure direct method will allow programming of the FPGA directly from the PCIe bus. If for some reason the XMC VLX does not perform as expected, you can power the XMC VLX down. Upon power-up, the example design provided by Acromag will again be loaded into the FPGA.

   The document, Using the XMC VLX Engineering Design Kit, provided in the engineering design kit will guide you through the steps required to modify the example design for your custom application.

   See the Direct PCIe bus to Xilinx Configuration section for a description of the steps required to perform reconfiguration directly from the PCIe bus. The registers provided in the FPGA Programming Memory Map are used to implement a direct reconfiguration.

3. After you have thoroughly tested your customized FPGA design, you can erase the flash and write your code to flash. Once the flash is erased you will not be able to go back to the example design by simply powering down and restarting the board.

   See the Flash Configuration section for a description of the steps required to write new or reprogram of example design code to the flash device. The registers provided in the FPGA Programming Memory Map are used to implement a flash erase and reprogram operations.

PCIe CONFIGURATION ADDRESS SPACE

This board is a PCI Express Base Specification Revision 1.1 compliant PCIe bus board.

The PCIe bus is defined to address three distinct address spaces: I/O, memory, and configuration space. This board can be accessed via the PCIe bus memory, and configuration spaces.

The card's configuration registers are initialized by system software at power-up to configure the card. The board is a Plug-and-Play PCIe card. As a Plug-and-Play card the board's base addresses are not selected via jumpers but are assigned by system software upon power-up via the configuration registers. A PCIe bus configuration access is used to read/write the PCIe card's configuration registers.

When the computer is first powered-up, the computer's system configuration software scans the PCIe bus to determine what PCIe devices are present. The software also determines the configuration requirements of the PCIe card.

The system software accesses the configuration registers to determine how many blocks of memory space the module requires. It then programs the board's configuration registers with the unique memory base address.

Since this board is relocatable and not fixed in address space, its device driver must use the mapping information stored in the board's Configuration Space registers to determine where the board is mapped in memory space.

The memory maps in this chapter reflect byte accesses using the "Little Endian" byte ordering format. Little Endian uses even-byte addresses to store the low-order byte. Little-Endian means that the least significant byte is stored at the lowest memory address and the most significant byte is stored at the highest memory address. The Intel x86 family of microprocessors uses "Little Endian" byte ordering.

Big Endian is the convention used in the Motorola 68000 microprocessor family and is the VMEbus convention. In Big Endian, the lower-order byte is stored at odd-byte addresses. Big-endian means that the most significant byte is stored at the lowest memory address and the least significant byte is stored at the highest memory address.

	Low address	Layout of a 64-bit long int						High address
Little Endian	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6	Byte 7
Big Endian	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0

CONFIGURATION REGISTERS

The PCIe specification requires software driven initialization and configuration via the Configuration Address space. This board provides 512 bytes of configuration registers for this purpose. It contains the configuration registers, shown in Table 3.1, to facilitate Plug-and-Play compatibility.

The Configuration Registers are accessed via the Configuration Address and Data Ports. The most important Configuration Registers are the Base Address Registers and the Interrupt Line Register which must be read to determine the base address assigned to the board and the interrupt request line that goes active on a board interrupt request.

Table 3.1 *Configuration Registers*

This board is allocated memory space address (BAR0) to access the PCIe interrupt, and DMA registers. The PCIe bus decodes 4K bytes for these memory space registers. .

This board is allocated a 4M byte block of memory (BAR2) that is addressable in the PCIe bus memory space. BAR2 space is used to access the board's flash configuration functions and the reprogrammable Virtex 5 FPGA registers.

In addition, this board is allocated (BAR4) memory of 8M bytes. The BAR4 memory is addressable in the PCIe bus memory space to access the board's Dual Port Memory transfers.

BAR0 MEMORY MAP

Table 3.2: *BAR0 Registers*

Note that any registers/bits not mentioned will remain at the default value logic low.

BAR0 Base Addr+	Bit(s)	Description
00H	31:0	Interrupt Control/Status
04H	31:0	DMA Status/Abort Register
08H	31:0	Global Interrupt Enable (Bit-31)
0CH -> FFH	31:0	Reserved
100H	31:0	DMA Channel 0 System Address LSB
104H	31:0	DMA Channel 0 System Address MSB
108H	31:0	DMA Channel 0 Transfer Size in bytes
10CH	7:0	DMA Channel 0 Command
110H	31:0	DMA Channel 0 XMC Board Starting Address
114H	0	DMA Channel 0 Start DMA Transfer Bit
118H to 11CH		Reserved
120H	31:0	DMA Channel 1 System Address LSB
124H	31:0	DMA Channel 1 System Address MSB
128H	31:0	DMA Channel 1 Transfer Size in bytes
12CH	7:0	DMA Channel 1 Command
130H	31:0	DMA Channel 1 XMC Board Starting Address
134H	0	DMA Channel 1 Start DMA Transfer Bit
138H	7:0	Retraining Counter
13CH->FFFH	31:0	Reserved

The BAR0 registers are implemented in the PCIe bus interface chip and not the user programmable FPGA. As such, the user cannot change the logic functions implemented in BAR0. These registers are read/write registers that are software controlled. These registers provide interrupt control/status and DMA control/status. The Interrupt Control/Status is at BAR0 base address plus 00H offset. The DMA registers are at BAR0 base address plus offset 100H to 134H. These registers control the transfer

direction, size, system address, and XMC addresses for DMA channels 0 and 1.

The Dual Port SRAM control registers at BAR2 must also be used to set up a DMA Demand Mode transfer. The Demand mode transfer is initiated by driving signals DREQ0# or DREQ1# active. The SRAM control register method allows a DMA transfer to be initiated when an FPGA generated address counter is equal to the DMA Channel Threshold Register. That is, when the predetermined amount of data is available in the SRAM the hardware will automatically start a DMA transfer.

Interrupt Control/Status Register (Read/Write) - (BAR0 + 00H)

INTERRUPT REGISTER

This Interrupt Control/Status register at BAR0 base address + offset 00H is used to monitor and clear pending board interrupts. An interrupt can originate from the two DMA channels or U7, the user-programmable FPGA. All board interrupts are enabled or disabled via bit-31 of the Global Interrupt Enable register at BAR0 + 08H.

Bit(s)	FUNCTION	
0	This bit when set indicates a pending board interrupt. It reflects a pending interrupt from DMA channel 0 or DMA channel 1 or the U7 FPGA. It will reflect this status even if the Board Interrupt enable bit-31 is disabled.	
	0	No Interrupt Pending
	1	Interrupt Pending
1	DMA Channel 0 Interrupt Pending Status. Bit-16 must be set to logic high for this bit to go active. Write logic high to clear bit.	
	0	No Interrupt Pending
	1	Interrupt Pending
2	DMA Channel 1 Interrupt Pending Status. Bit-17 must be set to logic high for this bit to go active. Write logic high to clear bit.	
	0	No Interrupt Pending
	1	Interrupt Pending
3	U7 Programmable FGPA Interrupt Pending Status. Bit-18 must be set to logic high for this bit to go active.	
	0	No Interrupt Pending
	1	Interrupt Pending
4-15	Not Used (bits are read as logic "0")	
16	DMA Channel 0 Interrupt Enable	
	0	DMA Channel 0 Interrupt Disabled
	1	DMA Channel 0 Interrupt Enabled
17	DMA Channel 1 Interrupt Enable	
	0	DMA Channel 1 Interrupt Disabled
	1	DMA Channel 1 Interrupt Enabled
18	U7 Programmable FPGA Interrupt Enable	
	0	Interrupt Disabled
	1	Interrupt Enabled
19-31	Not Used (bits are read as logic "0")	

Table 3.3: *Interrupt Control/Status Register When designing software drivers it is best to treat this register as two 16-bit registers. The upper 16-bits are Interrupt Control bits and the lower 16-bits are Interrupt Status.*

A board pending interrupt is identified via bit-0 of this register. Logic high on bit-0 indicates a board pending interrupt. Bit-0 indicates a pending interrupt as long as DMA Channel 0 or DMA Channel 1 or U7 Programmable FPGA interrupt pending status bits 1, 2, or 3 respectively, remain active.

A DMA channel 0 pending status can be cleared/released by writing logic high to bit-1, the interrupt pending status bit. Likewise, writing logic high to bit-2 of this register clears DMA channel 1 pending status. U7 Programmable FPGA interrupt Pending status will pass the interrupt status of U7 only when bit-18 is set to logic high.

The Software Reset and Status Register at BAR2 + 8000H can be read to identify the exact source of the Programmable Virtex-5 FPGA interrupt.

Bits 16 to 18 of this register are used to enable or disable interrupts from specific functions. This Interrupt register must have bits 16 and 17 set to logic high in order for DMA interrupts to occur on DMA channels 0 and 1, respectively. Bit-18 must be set to logic high to enable interrupts from U7, the programmable FPGA.

The mezzanine board interrupt enable bits must also be set if interrupts are to originate from the mezzanine board which are passed through the programmable FPGA to this register's pending status bits.

DMA BAR0 REGISTERS

DMA Status/Abort Register (Read/Write) - (BAR0 + 04H)

This DMA Status register at BAR0 base address plus 04H is used to identify a DMA transfer complete status and issue DMA channel abort.

The DMA complete status bit 0 or 1 will remain logic high until cleared by writing logic high back to the same bit. The start of a new DMA transfer (hardware initiated) will also clear a set Transfer Complete bit.

The DMA abort bits 8 and 9 corresponding to channels 0 and 1 respectively when set to logic high will abort the current DMA transfer. If asserted and the channel still has outstanding requests, all requests are handled before the transfer is aborted, otherwise the transfer is immediately aborted. If asserted, and the current transfer is a Completion, than a Completion with Completion Abort status is sent and the DMA transfer is stopped.

This register can be read or written via 32-bit transfers.

Bit(s)	FUNCTION	
0	DMA Channel 0 Transfer Complete. This bit is cleared by write of logic high to this bit or start of a new DMA transfer.	
	0	Transfer not Complete
	1	Transfer Completed
1	DMA Channel 1 Transfer Complete. This bit is cleared by write of logic high to this bit or start of a new DMA transfer.	
	0	Transfer not Complete
	1	Transfer Completed
2-7	Not Used (bits are read as logic "0")	
8	DMA Channel 0 Abort on write of logic high to this bit.	
	0	No Action
	1	Abort Channel 0 DMA transfer
9	DMA Channel 1 Abort on write of logic high to this bit.	
	0	No Action
	1	Abort Channel 1 DMA transfer
10-15	Not Used (bits are read as logic "0")	
16-19	DMA Channel 0 or State Encoding	
	0000	Transfer Completed Successfully
	0001	Transfer stopped by backend
	0010	Transfer ended with CPL timeout
	0011	Transfer ended with CPL UR error
	0100	Transfer ended with Completion error
	1000	Channel is busy
	1001	Requesting transfer to PCIe Link
	1010	Waiting for Completion
	1011	Waiting for backend read or write data
	11XX	Busy State reserved
20-23	DMA Channel 1 State Encoding (see bit descriptions given for Channels 0 on bits 16-19)	
24-31	Not Used (bits are read as logic "0")	

Table 3.4 *DMA Status Register*

DMA BAR0 REGISTERS

DMA transfers must start aligned to Double Lword boundary when performing 64-bit DMA transfers.

Global Interrupt Enable Bit-31 (Read/Write) - (BAR0 + 08H)

GLOBAL INTERRUPT ENABLE

This Global Interrupt Enable bit at BAR0 base address + offset 08H is used to enable all board interrupts. An interrupt can originate from the two DMA channels or U7, the programmable FPGA. All board interrupts are enabled when bit-31 is set to logic high. Likewise, board interrupts are disabled with bit-31 set to logic low. Bit-31 of this register can be read or written.

Bit(s)	FUNCTION	
0-30	Not Used (bits are read as logic "0")	
31	XMC Board Interrupt Enable. This bit must be set to enable the PCIe bus interrupt signal to be driven active by the board.	
	0	Board Interrupts Disabled
	1	Board Interrupts Enabled

Table 3.5 *Global Interrupt Enable Bit*

DMA System Starting Address LSB Registers (Read/Write) -
(BAR0 + 100H and 120H)

This register contains the least significant 32 address bits of the DMA System Starting Address.

The DMA System Starting Address register meaning depends on the selected DMA mode (see bit-3 of DMA command register). For Direct DMA Mode this address register specifies the physical address of a contiguous memory buffer where data will be read/written. For scatter-gather DMA mode this address register points to the first element of the chained-listed of page descriptors.

The DMA System Starting Address Register at BAR0 base address plus 100H (120H) is used to set the DMA channel 0 (1) data starting address. Writing to these registers is possible via 32-bit transfers.

DMA System Starting Address MSB Registers (Read/Write) -
(BAR0 + 104H and 124H)

This register contains the most significant 32 address bits of the DMA System Starting Address.

The DMA System Starting Address register meaning depends on the selected DMA mode (see bit-3 of DMA command register). For Direct DMA Mode this address register specifies the physical address of a contiguous memory buffer where data will be read/written. For scatter-gather DMA mode this address register points to the first element of the chained-listed of page descriptors.

The DMA System Starting Address Register at BAR0 base address plus 104H (124H) is used to set the DMA channel 0 (1) data starting address. Writing to these registers is possible via 32-bit transfers.

DMA Transfer Size Registers (Read/Write) -
(BAR0 + 108H and 128H)

The DMA Transfer Size Register is used to set the size of the DMA transfer that moves data between system memory and the board's Dual Port SRAM. The transfer size indicates to total amount of data to transfer, in units of bytes.

The onboard static RAM has 8-MegaByte maximum capacity. As such, the maximum value that should be written to this register is 800000 hex. The register is actually a 24-bit register and will accept a value up to FFFFFF hex. A value larger than 800000 hex will exceed the size of the available SRAM and must be avoided.

The DMA Transfer Size Register at BAR0 base address +108H (128H) is used to set the DMA channel 0 (1) data transfer size. Writing to these registers is possible via 32-bit data transfers.

DMA Command Registers (Read/Write) - (BAR0 + 10CH and 12CH)

The DMA Command register is used to set the priority, Scatter Gather enable, and to indicate the command to be used for the DMA transfer.

Memory Read Burst command is used to program a read transfer. The data is moved from system memory to the boards SRAM memory.

Memory Write Burst command is used to program a write transfer. The data moves from SRAM to system memory.

Writing to these registers is possible via 32-bit data transfers.

Bit(s)	FUNCTION	
0	Not Used (bit is read as logic '0')	
1	Not Used (bit is read as logic '0')	
2	Not Used (bit is read as logic '0')	
3	Scatter-gather: Setting this bit enables scatter-gather mode	
	0	Direct DMA Mode
	1	Enable Scatter-Gather Mode
7 to 4	DMA Command	
	'0110'	Memory Read Burst
	'0111'	Memory Write Burst
8 to 31	Not Used (bit is read as logic '0')	

***Table 3.6** DMA Command Register*

DMA transfers must start aligned to Double Lword boundary when performing DMA transfers.

In Scatter Gather DMA transfer mode, the DMA start address is a pointer to a chained list of page descriptors. Each descriptor contains the address and size of a data block (page), as well as the next descriptor block. The following table describes the 20 byte block Scatter Gather descriptor.

Offset	Field	Description
00H	Page Address 31:3	The Start address of memory page that must be aligned on an 8-byte boundary (bits2:0 must be "000") If a page is located in 32-bit address space, then bits 63:32 must be set to 0. If a page is located in 64-bit address space, then the full 64-bit address must be initialized.
04H	Page Address 63:32	
08H	Page Size 31:0	The size of the memory page in units of bytes and a multiple of 8 bytes.
0CH	Next Descriptor 31:2 Bit 0 is End of Chain bit	The address of the next page descriptor, which must be aligned on a 4-byte boundary (bits 1:0 must be "00"). Setting bit 0 to logic 1 indicates that the current descriptor is the last descriptor in the chain.
10H	Next Descriptor 63:32	

***Table 3.7:** Scatter Gather Descriptor Block*

DMA XMC Board Starting Address Registers (Read/Write) - (BAR0 + 110H and 130H)

The DMA XMC Board Starting Address register specifies the physical address of the board's Dual Port SRAM memory where data will be read/written.

Data bits 22 down to 2 of this register are used to address the SRAM. Data bit-2 select the low 32-bit SRAM (U4) when logic low and selects the upper 32-bit SRAM (U19) when logic high. Data bits 22 down to 3 correspond to SRAM address lines 19 down to 0.

The DMA XMC Board Starting Address register at BAR0 base address plus 110H (130H) is used to set the DMA channel 0 (1) data starting address. Writing to these registers is possible via 32-bit data transfers.

Start DMA Transfer (Write Only) - (BAR0 + 114H and 134H)

The Start DMA Transfer register is used to software start a DMA transfer. Set bit-0 to logic '1' will start the corresponding channels DMA transfer.

The Start DMA Transfer register at BAR0 base address plus 114H (134H) is used to start the DMA channel 0 (1) transfer. Writing to these registers is possible via 32-bit data transfers.

BAR2 MEMORY MAP

The memory space address map used to program the FPGA and flash device is shown in Table 3.8. Note that the base address for the board (BAR2) in memory space must be added to the addresses shown to properly access these registers. Register accesses as 32, 16, and 8-bit transfers in memory space are permitted. All addresses in BAR2 from 0 to 7FFF hex are fixed and cannot be changed by the user via the programmable Virtex-5 FPGA.

This memory map reflects byte accesses using the "Little Endian" byte ordering format. Little Endian uses even-byte addresses to store the low-order byte. The Intel x86 family of microprocessors uses "Little Endian" byte ordering. In Big Endian, the lower-order byte is stored at odd-byte addresses.

Flash Configuration

The VLX/VSX board uses a flash configuration device to store programming information for the Xilinx FPGA. The flash configuration device and FPGA are hardwired together so that during power-up the contents of the configuration device are downloaded to the FPGA. The flash configuration data can be reprogrammed using the PCIe bus interface. The following is the general procedure for reprogramming the flash memory and reconfiguration of the Xilinx FPGA:

1) Disable auto-configuration by setting bit-0 (Stop Configuration) of the Configuration Control register to logic high.
2) Clear the Xilinx FPGA of its previous configuration by setting the Configuration Control register bit-2 to logic high. Software must also keep bit-0 set to a logic high.
3) Read INIT as logic high (Bit-1 of Configuration Status register) before programming is initiated.
4) Verify that the Flash Chip is not busy by reading bit-7, of the Flash Status 2 register at base address plus 10H, as logic 0 before starting a new Flash operation.
5) Erase the current flash contents by using the Flash Erase Sector method. Flash erase sectors are implemented by setting bit-0 of the Flash Erase Sector register to logic high. There are 128 flash sectors, which are addressed via the most significant seven flash address lines. The most significant seven flash address lines are set via the Flash Address 23-17 register at base address plus 34H. Issuing a Flash Erase Sector command will erase the contents of the flash chip only in the sector specified.
6) Verify that the Flash Chip is not busy by reading bit-7, of the Flash Status 2 register at base address plus 10H, as logic 0 before going to the next step.
7) Download the Configuration file to the flash configuration chip via the PCIe bus.
   i) Write the byte to be sent to the Flash Data register at base address plus 28H.
   ii) Write the address of the Flash Chip to receive the new data byte to the Flash Address registers at base address plus 2CH, 30H, and 34H. Issuing a Flash Start Write will automatically increment this address after the prior Flash Write has been completed. Thus, the address will not need to be set prior to issuing the next Flash Start Write. The first byte of the configuration file should be written to address 0 of the Flash Chip. The Flash Start Write operation will take 9μ seconds to complete.
   iii) Issue a Flash Start Write command to the Flash Chip by writing logic 1 to bit-0 of base address plus 1CH.
   iv) Verify that the Flash Chip is not busy by reading bit-7 as logic 0 of the Flash Status 2 register at base address plus 10H before going back to step i to write the next byte.
8) Enable auto-configuration by setting bit-0 (Stop Configuration) of the Configuration Control register to logic low.

9) Verify that the configuration is complete by reading DONE (bit-0 of Configuration Status Register) as logic high.
10) Thereafter, at power-up the configuration file will automatically be loaded into the FPGA.

Direct PCIe bus to Xilinx Configuration

Configuration of the Xilinx FPGA can be implemented directly from the PCIe bus. The following is the general procedure for re-configuration of the Xilinx FPGA via the PCIe bus:

1) Disable auto-configuration by setting bit-0 (Stop Configuration) of the Configuration Control register to logic high.
2) Clear the Xilinx FPGA of its previous configuration by setting the Configuration Control register bit-2 to logic high.
3) Read INIT as logic high (Bit-1 of Configuration Status register) before programming is initiated.
4) Download the Configuration file directly to the Xilinx FPGA by writing to the Configuration Data register. The entire configuration file must be written to the Xilinx FPGA one byte at a time to the Configuration Data register at base address plus 08H.
5) Verify that the configuration is complete by reading DONE (bit-0 of Configuration Status Register) as logic high. DONE is expected to be logic high immediately after the last byte of the configuration file is written to the Xilinx FPGA.
6) At each power-up the configuration file will need to be reloaded into the FPGA.

CONFIGURATION CONTROL REGISTERS

Configuration Status Register (Read Only) – (BAR2 + 0000H)

This read only register reflects the status of configuration complete and Xilinx configuration clear bits. This Configuration Status register is read at base address plus 0H.

Table 3.9: *Configuration Status Register*

Bit(s)	FUNCTION	
0	DONE:	
	0	Xilinx FPGA is not configured
	1	Xilinx FPGA configuration is complete
1	INIT:	
	0	INIT is held low until the Xilinx is clear of its current configuration
	1	INIT transitions high when the clearing of the current Xilinx configuration is complete
2 to 7	Not Used (bits are read as logic "0")	

Configuration Control (Read/Write) – (BAR2 + 04H)

CONFIGURATION CONTROL REGISTERS

This read/write register is used to stop Xilinx configuration, and clear Xilinx configuration memory. This Configuration Control register is accessed at base address plus 04H.

Bit(s)	FUNCTION	
0	Stop Xilinx Configuration:	
	0	Enable Xilinx FPGA configuration
	1	Stop Xilinx FPGA configuration (This bit should be set to logic high until after the Flash device is written with valid program data).
1	Not Used (bit is read as logic "0")	
2	Clear Current Xilinx Configuration:	
	0	Logic low has no effect.
	1	Logic high resets the Xilinx configuration logic. Re-configuration can begin after INIT transitions high.
3 to 7	Not Used (bits are read as logic "0")	

Table 3.10: *Configuration Control Register*

Configuration Data (Write Only) – (BAR2 + 08H)

This write only register is used to write Xilinx configuration data directly to the Xilinx FPGA from the PCIe bus. The Configuration Data register is accessed at base address plus 08H. The entire configuration file must be written to the Xilinx FPGA one byte at a time. Configuration complete is verified by reading DONE (bit-0 of the Configuration Status Register) as logic high.

A write to the Configuration Data register while auto-configuration from Flash is active will cause the Xilinx configuration to fail. Auto-configuration is stopped by writing logic 1 to bit-0 of the Configuration Control register at base address plus 04H.

The Xilinx FPGA should also be cleared of its current configuration prior to loading of a new configuration file. The FPGA is cleared of its current configuration by writing logic 1 to bit-2 at address plus 04H.

Flash Status 1 (Read Only) – (BAR2 + 0CH)

FLASH CONTROL REGISTERS

This read only register is used to read the DQ5 status of the flash chip. The Flash Status 1 register is at base address plus 0CH.

Bit(s)	FUNCTION	
0 to 4	Not Used (bits are read as logic "1 or 0")	
5	DQ5:	
	0	Chip enabled for reading array data.
	1	The system must issue the Flash Reset command to re-enable the device for reading array data if DQ5 goes high. DQ5 will go high during a Flash Start Write, Flash Erase Chip, or Flash Erase Sector operation.
6 and 7	Not Used (bits are read as logic "1 or 0")	

Table 3.11: *Flash Status 1 Register*

FLASH CONTROL REGISTERS

Flash Status 2 (Read Only) – (BAR2 + 10H)

This read only register is used to read the ready or busy status of the flash chip. The Flash Status 2 register is at base address plus 10H. The system must first verify that that Flash Chip is not busy before executing a new Flash command. The Flash Chip is busy if bit-7 of this register is set to logic 1. The Flash will always be Busy while bit-0 of the Configuration Control register is set to logic "0".

Table 3.12: *Flash Status 2 Register*

Bit(s)	FUNCTION	
0 to 6	Not Used (bits are read as logic "0")	
7	Busy / Ready~ Set bit-0 of the Configuration Control register to logic "1" before monitoring this busy bit.	
	0	Flash Chip is Ready
	1	Flash Chip is Busy

Flash Read (Read Only) – (BAR2 + 14H)

A Flash Read command is executed by reading this register at base address plus 14H. Prior to issue of a Flash Read the Flash Address registers must be set with the desired address to be read. See the Flash Address registers at base address plus 2CH, 30H, and 34H.

The system must issue the Flash Reset command to re-enable the device for reading array data if DQ5 goes high. DQ5 can go high during a Flash Start Write, Flash Erase Chip, or Flash Erase Sector operation. DQ5 can be monitored via the Flash Status 1 register at base address plus 0CH.

Flash Reset (Write Only) – (BAR2 + 18H)

This write only register is used to initiate a reset of the flash chip. A Flash Reset command is executed by writing logic 1 to bit-0 of this register at base address plus 18H. Writing the flash reset command resets the chip to reading data mode. Flash reset can be useful when busy is held active.

Flash Start Write (Write Only) – (BAR2 + 1CH)

This write only register is used to initiate the write of a byte to the flash chip. A Flash Start Write command is executed by writing logic 1 to bit-0 of this register at base address plus 1CH. Prior to issuing of a Flash Start Write the Flash Data and Address registers must be set with the desired data and address to be written. See the Flash Data and Address registers at base address plus 28H, 2CH, 30H, and 34H.

Issuing of a Flash Start Write will automatically increment this address after the previously issued Flash Write has completed. Thus, the address will not need to be set prior to issuing of the next Flash Start Write if consecutive addresses are to be written.

Flash Erase Sector (Write Only) – (BAR2 + 20H)

A Flash Erase Sector command is executed by writing logic 1 to bit-0 of this register at base address plus 20H. Verify that the Flash Chip is not busy from a previous operation before beginning a new operation. This is accomplished by reading bit-7, of the Flash Status 2 register, as logic 0.

There are 128 flash sectors, which are addressed via the most significant seven flash address lines. The most significant seven flash address lines are set via the Flash Address 23-17 register at base address plus 34H. Issuing of a Flash Erase Sector command will erase the contents of the flash chip only in the sector specified.

A flash bit cannot be programmed from logic 0 to logic 1. Only an erase chip operation can convert logic 0 back to logic 1. **Prior to reprogramming of the flash chip a Flash Erase Chip or Flash Erase Sector command must be performed.**

The system can determine the status of the erase operation by reading the Flash Ready/Busy status. Bit-7 of the Flash Status 2 register, at base address plus 10H, will read as logic 0 when chip erase is completed.

Any other flash commands written to the flash chip during execution of the flash erase sector operation are ignored. Note that a hardware reset during the erase sector operation will immediately terminate the operation.

Flash Erase Chip (Write Only) – (BAR2 + 24H)

This write only register is used to erase the entire contents of the flash chip. A flash bit cannot be programmed from logic 0 to logic 1. Only an erase chip operation can convert logic 0 back to logic 1. **Prior to reprogramming of the flash chip a Flash Erase Chip command must be performed.**

A Flash Erase Chip command is executed by writing logic 1 to bit-0 of this register at base address plus 24H. Verify that the Flash Chip is not busy from a previous operation before beginning a new operation. This is accomplished by reading bit-7, of the Flash Status 2 register, as logic 0.

The system can determine the status of the erase operation by reading the Flash Ready/Busy status. Bit-7 of the Flash Status 2 register, at base address plus 10H, will read as logic 0 when chip erase is completed.

Any other flash commands written to the flash chip during execution of the flash erase chip operation will be ignored. Note that a hardware reset during the chip erase operation will immediately terminate the operation.

Flash Data Register (Read/Write) – (BAR2 + 28H)

This read/write register holds the data byte which is sent to the flash chip upon issuing of a Flash Start Write command.

Although only the least significant 8 bits of this register are used, reading or writing this register is possible via 32-bit, 16-bit or 8-bit data transfers.

FLASH REGISTERS

Flash Address 7->0 (Read/Write) – (BAR2 + 2CH)

This read/write register holds the least significant byte of the address to which the flash chip is written upon issue of a Flash Start Write command.

Although only the least significant 8 bits of this register are used, reading or writing this register is possible via 32-bit, 16-bit or 8-bit data transfers.

Flash Address 15->8 (Read/Write) – (BAR2 + 30H)

This read/write register sets bits 15 to 8 of the address to which the flash chip is written upon issue of a Flash Start Write command.

Although only the least significant 8 bits of this register are used, reading or writing this register is possible via 32-bit, 16-bit or 8-bit data transfers.

Flash Address 23->16 (Read/Write) – (BAR2 + 34H)

This read/write register sets bits 23 to 16 of the address to which the flash chip is written upon issue of a Flash Start Write command.

Reading or writing this register is possible via 32-bit, 16-bit or 8-bit data transfer.

SYSTEM MONITOR REGISTERS U5 PCIe bus

System Monitor Status/Control Register (Read/Write) – (BAR2 + 38H)

This read/write register will access the system monitor register at the address set in the System Monitor Address Register.

For example, the address of the System Monitor Status register that is to be accessed is first set via the System Monitor Address register at BAR2 plus 3CH. Next, this register at BAR2 plus 38H is read. Bits 22 to 16 of this register hold the address of system monitor register that is accessed. Data bits 15 to 6 of this register hold the temperature, Vccint, or Vccaux value. Data bits 5 to 0 are not used. Valid addresses are given in column one of Table 3.12.

Reading or writing this register is possible via 32-bit data transfers.

The 10-bits digitized and output from the ADC can be converted to temperature by using the following equation.

$$Temperature(^{\circ}C) = \frac{ADCcode \times 503.975}{1024} - 273.15$$

The 10-bits digitized and output from the ADC can be converted to voltage by using the following equation.

$$SupplyVoltage(volts) = \frac{ADCcode}{1024} \times 3V$$

System Monitor Address Register (Write Only) – (BAR2 + 3CH)

This write only register is used to set the system monitor address register with a valid address for the System Monitor internal status or control registers. Valid addresses are given in the following table. Additional addresses can be found in the Xilinx System Monitor document UG192 (available from Xilinx). Writing this register is possible via 32-bit data transfers.

The address value written to this register can be read on bits 22 to 16 of the System Monitor Status/Control register at BAR2 plus 38H.

Address	Status Register
00h	Temperature
01h	Vccint
02h	Vccaux
20h	Maximum Temperature
21h	Maximum Vccint
22h	Maximum Vccaux
24h	Minimum Temperature
25h	Minimum Vccint
26h	Minimum Vccaux

Table 3.13: *System Monitor Register Map*

Software Reset and Status Register (Read/Write) – (BAR2 + 8000H)

BAR2 U7 FPGA REGISTERS

This read/write register is used to Software reset the board, monitor the status of board interrupts, and select the on board active clock.

Bits 0 to 7 of this register are used to monitor the interrupt pending status of interrupts originating from the front mezzanine module.

USERo CLOCK CONTROL

Bit 8 of this register controls the USERo signal. The USERo control signal is used to select between the 125MHz clock and the user defined clock (PLL_CLK). The user defined clock is defined in the example code of the FPGA and output on signal PLL_CLK. The Digital Clock Manager of the FPGA offers a wide range of clock management features including clock multiplication and division for generation of a user defined clock (PLL_CLK). A 125MHz crystal generated clock signal (FPGA_CLK_PLL) is input to the FPGA for use in generation of the user-defined clock signal PLL_CLK. The PLL_CLK can be a minimum of 62.5MHz and a maximum of 125MHz. Since the PLL_CLK signal is generated and driven by the FPGA, it will only be available after the FPGA is configured. See the example VHDL file included in the engineering design kit and the Xilinx documentation on the Digital Clock Manager for more information.

Note USERo selects the Local bus clock.

The USERo signal is controlled via a bit-8 of the Software Reset and Status Register at BAR2 plus 8000H. The USERo control bit-8 at by default is set to a logic low to select the PLL_CLK clock as the board clock frequency. Bit-8 set to logic high will select the 125MHz clock as the board clock frequency.

Bits 15 to 13 of this register will read "001" for all Acromag digital I/O mezzanine modules. These bits will read "010" when the AXM-A30 high speed analog input mezzanine module is present.

Bits 27 and 28 are DMA acknowledgement bits and will read a logic high while the corresponding DMA channel transfer is active.

Bit-29 indicates the completion of initialization and calibration of the DDR2 controller.

Bit 31 of this register when set to a logic "1" will issue a reset signal to the FPGA hardware.

Reading or writing to this register is possible via 32-bit, 16-bit or 8-bit data transfers.

Table 3.14: *Software Reset and Status Register*

1. *All bits labeled "Not Used" will return logic "0" when read.*

BIT	FUNCTION	
7-0	Mezzanine interrupt status is identified via data bits 0 to 7. Read of a "1" indicates that an interrupt is pending for the corresponding data bit. A pending interrupt will remain active until disabled via the mezzanine interrupt control registers.	
	Logic "0"	Interrupt Not Pending
	Logic "1"	Interrupt Pending
8	USERo Control	
	Logic "0"	Board clock = PLL_CLK (Default)
	Logic "1"	Board clock 125MHz
12-9[1]	Not Used[1]	
15-13	Mezzanine Identification Code: "001" for all Acromag digital I/O mezzanine boards "010" for the AXM-A30 mezzanine board	
26-16	Not Used[1]	
27	DACK0 Status Logic high is a valid acknowledgement for DMA channel 0	
28	DACK1 Status Logic high is a valid acknowledgement for DMA channel 1	
29	Phy_init_done Status	
30	Not Used[1]	
Bit-31	The most significant bit of this register when set to a logic "1" will issue a software reset.	
	Logic "0"	No Operation
	Logic "1"	Software reset issued to Xilinx user-programmable FPGA

REAR Read REGISTER

Rear I/O Connector Read Register (Read Only) - (BAR2 + 802CH)

The Rear I/O Connector Read Register is used to read the LVDS input status of 16 channels. This example design has 16 channels, identified in Table 3.14, programmed as LVDS input only channels. Table 2.1 shows each channel and it's corresponding P4 connector pin assignment.

This Rear I/O Connector Read register is a read only register and writing to this register has no effect on the LVDS input channels. Reading from this register is possible via 32-bit, 16-bit or 8-bit data transfers.

REAR Write REGISTER

Rear I/O Connector Write Register (Read/Write) - (BAR2 + 8030H)

The Rear I/O Connector Write Register is used to set 16 LVDS output channels. This example design has 16 channels, identified in Table 3.11, fixed as LVDS output only channels. Table 2.1 shows the P4 connector pins and their corresponding channel identifiers.

This Rear I/O Connector Write register is written to set the LVDS output channels and can also be read to verify the output channel settings. Reading from this register is possible via 32-bit, 16-bit or 8-bit data transfers.

Write/Read Data Register Bit	Rear Connector Write Output Channels	Rear Connector Read Input Channels
0	1	0
1	2	3
2	4	5
3	6	7
4	8	9
5	10	11
6	12	13
7	14	15
8	16	17
9	18	19
10	20	21
11	22	23
12	24	25
13	26	27
14	28	29
15	30	31
16-31	Not Used[1]	Not Used[1]

Table 3.15: *Rear I/O Registers*

Column 1 identifies the write data bit that drives the output channel listed in column 2. Column 1 also identifies the read data bit that returns the input channel listed in column 3. For example data bit 0 drives output channel 1 when written and returns channel 0 register setting when read.

1. *All bits labeled "Not Used" will return logic "0" when read.*

DMA REGISTERS AT BAR2

DMA Control Register (Read/Write) - (BAR2 + 8034H)

The DMA Control Register is used to request a DMA Demand mode transfer. The hardware signals **DREQ0 and DREQ1** are driven active by software setting of bits 0 or 1 of this register to request the DMA transfer. The transfer must include the Static RAM Memory as either the source or the destination.

For software triggered DMA, bit-0 is used to request a DMA channel 0 transfer while bit-1 is used to request a channel 1 transfer. The bit must be set to logic high to request a transfer. Once set, the bit will remain asserted until the DMA transfer has started. If both bits are set simultaneously, the channel 0 DMA transfer will be implemented first followed by channel 1.

In a user application a data ready condition, such as a memory buffer full condition, can be physically tied (via logic in the FPGA) to the DREQ0 or DREQ1 FPGA signals to cause the DMA transfer to start.

Signals DACK0_n and DACK1_n, input to the programmable FPGA from the bus interface FPGA U5, are held active during a DMA transfer. These signals are not accessible via a register but can be used in custom firmware.

The DMA Status/Abort register at BAR0 plus 04H register bits 0 and 1 can be used to identify DMA transfer complete status.

DUAL PORT SRAM REGISTERS

FPGA- SRAM Data Register (Read/Write) – (BAR2 + 8038H and 803CH)

The FPGA-SRAM Data Read Register is provided to access the SRAM port that links directly to the user-programmable Virtex-5 FPGA. Reading or writing BAR2 + 8038H accesses the SRAM least significant data lines 31 to 0. Reading or writing BAR2+ 803CH accesses the most significant SRAM data lines 63 to 32. Reading or writing these registers is only possible in 32-bit transfers. The address for the SRAM read or write is initialized by the Dual Port SRAM Internal Address register at BAR2 + 8044H. With each additional read or write to BAR2+ 803CH the address is automatically incremented.

Writing the SRAM would proceed by first setting the Address register at BAR2 + 8044H. Next the least significant 32-bit data word is written to BAR2 + 8038H. Finally, after the most significant 32-bit data word is written at BAR2+ 803CH the address is automatically incremented.

FPGA-Port SRAM Control Register (Read/Write) – (BAR2 + 8040H)

This read/write register is used to control the Dual-Port SRAM including enabling write, automatic DMA transfer and automatic address reset on DMA thresholds.

The default power-up state of this register is logic low. A reset will set all bits in this register to "0". Reading or writing to this register is possible via 32-bit, 16-bit or 8-bit data transfers.

BIT	FUNCTION	
0	This bit controls the vhdl signal SRAM_ENABLE. This signal must be set to logic high to enable writes to SRAM from the FPGA. The SRAM Internal Address register must also be set with the start address at which the data begins filling the SRAM.	
	Logic "0"	Disable Write and Enable Read
	Logic "1"	Enable Write and Disable Read
1	If enabled via this bit a DMA channel 0 request will be issued when the internal address counter is equal to the DMA Channel 0 Threshold Register. This will have the same effect as writing a 1 to bit 0 of the DMA Control Register at BAR2 plus 8034H. See Synchronous DP-SRAM in Section 4.0 for further details on using this feature.[2]	
	Logic "0"	Disable Auto DMA Request Channel 0
	Logic "1"	Enable Auto DMA Request Channel 0
2	If enabled via this bit a DMA Channel 1 request will be issued when the internal address counter is equal to the DMA Channel 1 Threshold Register. This will have the same effect as writing a 1 to bit 1 of the DMA Control Register at BAR2 plus 8034H.[2]	
	Logic "0"	Disable Auto DMA Request Channel 1
	Logic "1"	Enable Auto DMA Request Channel 1
3	If enabled via this bit the Internal Address Counter will be loaded with the value in Address Reset Register 0 when the counter is equal to the DMA Channel 0 Threshold Register. See the Address Reset Register description for further details. DMA does not have to be enabled to use this feature.[3]	
	Logic "0"	Disable Add. Reset on DMA Ch. 0 Threshold
	Logic "1"	Enable Add. Reset on DMA Ch. 0 Threshold
4	If enabled via this bit the Internal Address Counter will be loaded with the value in Address Reset Register 1 when the counter is equal to the DMA Channel 1 Threshold Register. See the Address Reset Register description for further details. DMA does not have to be enabled to use this feature.[3]	
	Logic "0"	Disable Add. Reset on DMA Ch. 1 Threshold
	Logic "1"	Enable Add. Reset on DMA Ch. 1 Threshold
5-15	Not Used[1]	

Table 3.16: *FPGA-Port SRAM Control Register*

1. *Bits are not used and will return logic "0" when read.*

2. *All DMA transfer settings in the DMA Registers at BAR0 should be set prior to enabling automatic DMA transfers.*

3. *WARNING: Before enabling Address Reset on DMA Thresholds (bits 3 & 4), verify that the "DMA Ch. 0 Threshold Register" is not equal to the "Address Reset Register 0" and the "DMA Ch. 1 Threshold Register" is not equal to the "Address Reset Register 1." If these registers are equal and automatic reset is enabled an infinite loop will be created within the internal logic of the FPGA.*

DP-SRAM REGISTERS

Warning: To guarantee functionality disable DP-SRAM write cycles (via bit 0 of the DP-SRAM Control Registers) before writing to the DP-SRAM Internal Address Register.

FPGA-Port SRAM Internal Address Register (Read/Write) – (BAR2 + 8044H)

The FPGA-Port SRAM Internal Address Register is used to view and set the internal SRAM address. The FPGA will only write using 64-bit data transfers allowing for FFFFF hex unique memory accesses. **Reading** this register will return the internal SRAM address. *Due to delays during data processing and the PCIe transfer the actual internal address may be slightly greater than the address read.* **Writing** to this register will set the Internal SRAM Address to the provided value. Bits 0 to 19 of this register are used. Writing logic '1' to bit 31 of this register or a system reset will cause the Internal SRAM Address to reset to "00000H" (the start of the SRAM memory). **Reading or writing to this register is possible via 32-bit data transfers, only.**

The SRAM Internal Address will automatically be incremented upon a write or read of the most significant SRAM Data Port at BAR2+ 803CH.

Table 3.17: *FPGA-Port SRAM Internal Address Register*

FPGA-Port SRAM Internal Address Register		
D31	**D30-D20**	**D19-D0**
SRAM Internal Address Reset	Not Used (Read as logic '0')	SRAM Internal Address

Note: An SRAM DMA Request will occur only <u>after</u> a data write cycle to the address defined by the DMA Threshold Registers.

FPGA-Port SRAM DMA Channel 0/1 Threshold Registers (Read/Write) – (BAR2 + 8048H/ 804CH)

The FPGA-Port SRAM DMA Channel 0/1 Threshold Registers are used to initiate an automatic DMA transfer. When the internal address counter is equal to the value in the DMA Channel 0 Threshold Register, a Channel 0 DMA request will be initiated. Similarly, when the internal address counter is equal the value in the DMA Channel 1 Threshold Register and there is valid data at that address, a Channel 1 DMA request will be initiated. This feature must be enabled via bits 1 and 2 (for Channels 0 & 1, respectively) of the FPGA-SRAM Control Register. Note that DMA settings must be set prior to the initiated transfer on both the BAR0 and BAR2 registers. A DMA transfer in progress is indicated via bits 0 and 1, for DMA Channels 0 and 1, respectively, in the DMA Control Register. See the DMA Registers section of this manual for further details. **Reading** of the Threshold register will return the corresponding DMA Threshold. **Writing** the Threshold registers will set the corresponding DMA Threshold to the provided value. Bits 0 to 19 of this register are used. **Reading or writing to this register is possible via 32-bit data transfers only.**

FPGA-Port SRAM DMA Channel 0/1 Threshold Registers		
Register	**D30-D20**	**D19-D0**
DMA Channel 0 Threshold Reg.	Not Used (Read as logic '0')	7FFFFH
DMA Channel 1 Threshold Reg.	Not Used (Read as logic '0')	FFFFFH

Table 3.18: *Dual-Port DMA Threshold Registers*

DP-SRAM REGISTERS

FPGA-Port SRAM Address Reset Registers 0/1 (Read/Write) – (BAR2 + 8050H/ 8054H)

The FPGA-Port SRAM Address Reset Registers are used to reset the internal address counter to a user-defined value immediately upon reaching the DMA Threshold value. For example, after an SRAM write cycle where the internal address counter is equal to the value defined in the DMA Channel 0 Threshold Register, the internal address counter will then be loaded with the value defined in the Address Reset Register 0. Similarly, after a SRAM write cycle where the internal address counter is equal to the value defined in the DMA Channel 1 Threshold Register, the internal address counter will then be loaded with the value defined in the Address Reset Register 1. This allows for the internal address counter to be changed without any interruption in the transfer of data from the front connector input to the DP-SRAM. This feature must be enabled via bits 3 and 4 (for Channel 0 & 1 thresholds, respectively) of the FPGA Port-SRAM Control Register. Note that the DMA transfers *do not* have to be enabled for this feature to function. **Reading** of either register will return the corresponding internal address reset value. **Writing** this register will set the corresponding internal address reset register to the provided value. Bits 0 to 19 of this register are used. The most significant bits are not used and will return logic '0' when read. A system reset will cause these registers to reset to "00000H".

WARNING: The "DMA Ch. 0 Threshold Register" must not equal the "Address Reset Register 0" and the "DMA Ch. 1 Threshold Register" must not equal the "Address Reset Register 1." If these registers are equal and the address reset is enabled via the FPGA Port-SRAM Control Register an infinite loop will be created within the internal logic of the FPGA.

ID Code REGISTER

XMC Board Identification Code Register (Read Only) - (BAR2 + 8058H)

The XMC Board Identification Code register at BAR2 plus 8058H stores an ID code that can used to uniquely identify the XMC Virtex 5 card. This register will read A3 hex as provided by the Acromag example design. The user can change the hardware setting of this register in the programmable FPGA code. This ID code can be used to properly assign software drivers to multiple XMC boards that may have the same device and vender ID in a given system.

Reading from this register is possible via 32-bit, 16-bit or 8-bit data transfers.

DDR-SDRAM REGISTERS

DDR SDRAM Control Register (Read/Write) –(BAR2 + 805CH)

This read/write register is used to control burst read or write to DDR SDRAM. In addition a DDR-SDRAM error status bit is. The DDR-SDRAM is set for a burst length of four and will require the DDR-SDRAM Write register to be preloaded with four 32-bit data values prior to issuing the write operation. The DDR-SDRAM Read register will contain four 32-bit data values following the issue of a read operation. For either a read or write the DDR-SDRAM Address register must be written with the desired command and address location for the access.

Table 3.19: *DDR-SDRAM Control Register*

BIT	FUNCTION	
0	Start DDR-SDRAM write operation. The DDR-SDRAM Write and Mask registers must first be written with the desired data that are to be burst out to the DDR-SDRAM. In addition, the DDR-SDRAM Address register must be written with the write address and command prior to setting this bit.	
	Logic "0"	No operation performed
	Logic "1"	Write Transfer Performed
1	Start DDR-SDRAM read operation. The Address Register must be written with the start address location and the read command prior to setting this bit. The DDR-SDRAM Read registers are filled with four data words that are read in a burst from the DDR-SDRAM.	
	Logic "0"	No operation performed
	Logic "1"	Read Transfer Performed
2-25	Not Used[1]	
26	WDF_Almost_Full: DDR Write data FIFO is almost full when this bit is Logic "1". Software can monitor to avoid over filling the write data FIFO.	
27	AF_Almost_Full: DDR Address FIFO is almost full when this bit is Logic "1". Software can monitor to avoid over filling the DDR Address FIFO.	
28-31	Not Used[1]	

1. *All bits labeled "Not Used" will return logic "0" when read.*

DDR SDRAM Address Register (Read/Write) –(BAR2 + 8060H)

This read/write register is used to set the DDR-SDRAM column address, row address, bank, chip select, and command. This register must be written prior to initiating a DDR-SDRAM read or write burst transfer via bits 0 or 1 of the DDR-SDRAM Control register.

BIT	FUNCTION	
A9-A0	DDR-SDRAM Column address is written to these bits. A column address is required when a read or write command is present on bits 29 to 31. There are 1024 unique columns.	
A22-A10	The DDR-SDRAM Row address is written to these bits. There are 8192 unique rows,	
A24,A23	The DDR-SDRAM Bank address (BA1, BA0) is written to these bits. The DDR-SDRAM has four unique banks.	
A28-A25[1]	Not Used[1]	
A31-A29	DDR-SDRAM Command	
	Logic "000"	**Write** The write burst access is initiated to the row given on bits A10 to A22. The value on A24 and A23 selects the bank address (BA1 and BA0), while the value on A9 to A0 selects the starting column location.
	Logic "001"	**Read** The read burst access is initiated to the row given on bits A10 to A22. The value on A24 and A23 selects the bank address (BA1 and BA0), while the value on A9 to A0 selects the starting column location.
	Logic "010" To "111"	Invalid combinations. Functionality of the controller is unpredictable for these commands.

Table 3.20: *DDR-SDRAM Address/Command Register*

1. *All bits labeled "Not Used" will return logic "0" when read.*

DDR SDRAM Read Registers (Read Only) – (BAR2 + 8064H to 8070H)

The four DDR-SDRAM Read registers are read only and hold the last four data values read from the DDR-SDRAM. The DDR-SDRAM is set for a burst of four for the purposes of this design example.

A DDR-SDRAM read is implemented by executing the following steps.

a) Set the DDR-SDRAM Address register with the starting address location and read command. Write the following value to the SDRAM Address Register at 8060H.

A31-A29	A28-A25	A24,A23	A22-A10	A9-A0
001	X	Bank	Row	Column

b) Set the start read bit of the DDR-SDRAM Control register at base address + 805C. Set bit-1 of the SDRAM Control Register at 805CH to logic high.

The data is read from the SDRAM and moved to the SDRAM Read Registers at 8064H to 8070H. Read of these registers directly after write of logic 1 to the SDRAM Control Register at 805CH can result in a read error. To ensure the SDRAM data has been written into the Read register, a 500ns delay after issue of start read via the DDR-SDRAM Control register may be necessary. Reading these registers is possible via 32, 16 or 8-bit transfers.

Table 3.21: *DDR-SDRAM Read Registers*

DDR SDRAM Read Registers		
Base Addr+	**D31-D0**	**Base Addr+**
8067	DDR-SDRAM Read Register D0	**8064**
806B	DDR-SDRAM Read Register D1	**8068**
806F	DDR-SDRAM Read Register D2	**806C**
8073	DDR-SDRAM Read Register D3	**8070**

DDR SDRAM Write Registers (Read/Write) – (BAR2 + 8074H to 8080H)

The four DDR-SDRAM Write registers hold four data values that are to be written to the DDR-SDRAM. The DDR-SDRAM is set for a burst of four for the purposes of this design example.

A DDR-SDRAM write is implemented by executing the following steps.

1) Write the four 32-bit data values that are to be written to the DDR-SDRAM to the registers at base address + 8074H to 8080H.

DDR SDRAM Write Registers		
Base Addr+	**D31-D0**	**Base Addr+**
8077	DDR-SDRAM Write Register D0	**8074**
807B	DDR-SDRAM Write Register D1	**8078**
807F	DDR-SDRAM Write Register D2	**807C**
8083	DDR-SDRAM Write Register D3	**8080**

Table 3.22: *DDR-SDRAM Write Registers*

2) Set the DDR-SDRAM Mask bits as desired at base address + 8084H. A value of 0H would enable all bytes to be written.

3) Issue the Write Command

   a) Set the DDR-SDRAM Address register with the starting address location and write command. Write the following value to the SDRAM Address Register at 8060H.

A31-A29	A28-A25	A24,A23	A22-A10	A9-A0
000	X	Bank	Row	Column

   b) Set the start write bit of the DDR-SDRAM Control register at base address + 805C. Set bit-0 of the SDRAM Control Register at 805CH to logic high.

DDR SDRAM Mask Register (Read/Write)–(BAR2 + 8084H)

The DDR-SDRAM mask register holds the write mask data bits that accompany the write data as it is written to the DDR-SDRAM. If a given data mask (DM) bit is set low, the corresponding data will be written to memory; if the DM bit is set high, the corresponding data will be ignored, and a write will not be executed to that byte location. The DDR-SDRAM is set for a burst of four for the purposes of this design example.

Table 3.23: *DDR-SDRAM Mask Register*

DDR SDRAM Mask Register Bit	Write Register	Byte Masked
0	D0	Byte 0 (D0 to D7)
1		Byte 1 (D8 to D15)
2		Byte 2 (D16 to D23)
3		Byte 3 (D24 to D31)
4	D1	Byte 0 (D0 to D7)
5		Byte 1 (D8 to D15)
6		Byte 2 (D16 to D23)
7		Byte 3 (D24 to D31)
8	D2	Byte 0 (D0 to D7)
9		Byte 1 (D8 to D15)
10		Byte 2 (D16 to D23)
11		Byte 3 (D24 to D31)
12	D3	Byte 0 (D0 to D7)
13		Byte 1 (D8 to D15)
14		Byte 2 (D16 to D23)
15		Byte 3 (D24 to D31)
16-31	Not Used[1]	

2. All bits labeled "Not Used" will return logic "0" when read.

Read or writing this register is possible via 32, 16 or 8-bit transfers.

SYSTEM MONITOR REGISTERS U7 FPGA

System Monitor Status/Control Register (Read/Write) – (BAR2 + 8088H)

This read/write register will access the system monitor register at the address set in the System Monitor Address Register at BAR2 plus 808CH.

For example, the address of the System Monitor Status register that is to be accessed is first set via the System Monitor Address register at BAR2 plus 808CH. Next, this register at BAR2 plus 8088H is read. Bits 22 to 16 of this register hold the address of the system monitor register that is accessed. Data bits 15 to 6 of this register hold the temperature, Vccint, or Vccaux value. Data bits 5 to 0 are not used. Valid addresses are given in column one of Table 3.23.

Reading or writing this register is possible via 32-bit data transfers.

The 10-bits digitized and output from the ADC can be converted to temperature by using the following equation.

$$Temperature(^{\circ}C) = \frac{ADCcode \times 503.975}{1024} - 273.15$$

The 10-bits digitized and output from the ADC can be converted to voltage by using the following equation.

$$SupplyVoltage(volts) = \frac{ADCcode}{1024} \times 3V$$

System Monitor Address Register (Write Only) – (BAR2 + 808CH)

This write only register is used to set the system monitor address register with a valid address for the System Monitor internal status or control registers. Valid addresses are given in the following table. Additional addresses can be found in the Xilinx System Monitor document UG192 (available from Xilinx). Reading or writing this register is possible via 32-bit data transfers.

The address value written to this register can be read on bits 22 to 16 of the System Monitor Status/Control register at BAR2 plus 8088hex.

Address	Status Register
00h	Temperature
01h	Vccint
02h	Vccaux
20h	Maximum Temperature
21h	Maximum Vccint
22h	Maximum Vccaux
24h	Minimum Temperature
25h	Minimum Vccint
26h	Minimum Vccaux

Table 3.24: *System Monitor Register Map*

DUAL PORT MEMORY

STATIC RAM MEMORY

A 1Meg x 64-bit Dual Port synchronous SRAM (DP-SRAM) is provided on the VLX/VSX board. One port of the SRAM connects directly to the local bus to allow for PCIe access. The remaining port connects directly with the user-programmable FPGA. This design allows for the user to maximize data throughput between the Field I/O's and the controlling processor.

There are two automatic DMA initiators available that will trigger upon a user set threshold. Furthermore, upon a DMA transfer, the internal counter can be reset to a user specified value. See DMA Registers for more information on these operations. These features can be individually controlled through the SRAM Control Registers.

Static RAM Memory (Read/Write) – (BAR4 + 000000H to 7FFFFFH)

BAR4 MEMORY MAP

The Static RAM memory space is used to provide read or write access to on board SRAM memory. This memory space allows access to the SRAM from the port on the PCIe bus side of the SRAM. The Static RAM device has a 1Meg x 64-bit capacity. Reading or writing to this memory space using DMA access is also only possible via 64-bit transfers.

The FPGA-Port SRAM Register at BAR2 + 8038H and 803CH are provided for testing the SRAM port that links directly to the user-programmable Virtex-5 FPGA.

4.0 THEORY OF OPERATION

This section contains information regarding the design of the board. A description of the basic functionality of the circuitry used on the board is also provided. Refer to the Block Diagram shown in Drawing 4502-131 as you review this material.

PCIe INTERFACE LOGIC

The PCIe bus interface logic on this board provides a 2.5Gbps interface to the carrier/CPU board per PCI Express Specification 1.1. The interface to the carrier/CPU board allows complete control of all board functions.

The PCIe bus endpoint interface logic is contained within a user interface FPGA. This logic includes support for PCIe commands, including: configuration read/write, and memory read/write. In addition, the PCIe interface requester and or completion accesses. Payload of up to 256 bytes is supported.

The logic also implements interrupt requests via message signaled interrupts. Messages are used to assert and de-assert virtual interrupt lines on the link to emulate the Legacy PCI interrupt INTA# signal.

The board perform DMA transfers on channels 0 and 1. The DMA transfers can be started via software or hardware. Hardware signal DREQ0# driven active by the programmable FPGA will start a DMA channel 0 transfer. Hardware signal DREQ1# driven active will start a DMA channel 1 transfer. To identify the pins corresponding to these signals, see the user constraints (.UCF) file provided in the engineering design kit. The DACK0# and DACK1# signals will go active upon the start of a DMA transfer and remain active until its completion. The example device driver software (purchased separately) can be used to exercise DMA block (software) and demand (hardware) modes of operation.

SYNCHRONOUS Dual-Port SRAM

A 1Meg x 64-bit synchronous Dual-Port SRAM is provided on the board. One port of the SRAM interfaces to the PCIe bus interface chip, the Xilinx Virtex-5 LX30T device (U5). The other port connects directly to the programmable FPGA (U7). This configuration allows for a continuous data flow from the field inputs through the FPGA to the SRAM and then to the PCIe bus. Both ports of the SRAM operate in Pipeline mode. This allows for faster operational speed but does cause a one-cycle delay during read operations. The pins corresponding to the control signals, address, and data buses are in the user constraint (.UCF) file provided in the engineering design kit.

The SRAM port connected directly to the user-programmable FPGA (U7) supports continuous writes or single cycle reads. The SRAM port connected to the PCIe bus, through U5, supports reading and writing using a burst, double word (4 byte), or DMA transfers. For double word (4byte) accesses address and control signals are applied to the SRAM during one clock cycle, and either a write will occur on the next cycle or a read in two clock cycles. DMA accesses operate using the continuous burst method for maximum data throughput. The control signal, starting address, and data (if writing) are applied to the SRAM during one clock cycle. Then, during a write DMA transfer, new data is applied to the bus every subsequent clock cycle until the transfer is complete.

THEORY OF OPERATION CONTINUED

DDR2 SDRAM

The board contains two 32M x 16-bit DDR2 SDRAM devices. The DDR2 SDRAM uses a double data rate architecture to achieve high-speed operation. The double data rate architecture has an interface designed to transfer two data words per clock cycle.

DQS is edge-aligned with data for reading data and center-aligned with data for writing data. The DDR2 SDRAM provides for programmable read or write burst lengths of four locations. The example design provided by Acromag is designed for a fixed burst length of four. A burst length of 8 is also available but not supported by the Acromag example design.

The DDR2 SDRAM operates from a differential clock (DDR2_CK and DDR2_CK_n); the crossing of DDR2_CK going HIGH and DDR2_CK_n going LOW will be referred to as the positive edge of DDR2_CK. Commands (address and control signals) are registered at every positive edge of DDR2_CK. Input data is registered on both edges of DQS, and output data is referenced to both edges of DQS as well as to both edges of DDR2_CK.

Local Bus Signals

The local bus interface between the PCIe bus interface chip (U5) and the user-programmable FPGA (U7) consists of the following signals.

The Local Address bus (LA) bits 21 to 2 are used to decode the 4M byte address space allocated by the PCIe bus to BAR2. Also, LA(26) bit-26 of the local address bus is logic high when the PCIe bus is performing an access to BAR2 address space.

LBE0_n, LBE1_n, LBE2_n and LBE3_n are the local bus byte enables. LBE0_n, when logic low, indicates that the least significant byte on data lines D7 to D0 is selected for the read or write transfer. Likewise LBE3_n when logic low indicates that the most significant byte on data lines D31 to D24 is selected for the read or write transfer.

The Local Data (LD) bus bits 31 to 0 are bi-directional signals used for both read and write data transfers.

ADS_n, the address data strobe signal, will pulse low for one local bus clock cycle at the start of a new read or write access. The ADS_n signal is driven by the PCIe bus interface chip (U5).

Readyn must be driven low, on read or write cycle, by the programmable FPGA (U7) and held low until Rdyack_n is driven low by the PCIe bus interface chip (U5). This is shown on the read and write diagrams that follow.

Rdyack_n is driven low by the PCIe bus FPGA (U5) to signify the end of the read or write cycle.

The LW_R_n signal, when logic high, indicates a write transfer in which data is moving from the PCIe bus to the reprogrammable FPGA (U7). This signal, when logic low, indicates a read transfer in which data is moving from the reprogrammable FPGA (U7) to the PCIe bus.

For a read cycle the LD data signals should be driven active prior to driving Readyn active. LD and Readyn should be held active until Rdyack_n is detected active.

The LA, LBE0_n, LBE1_n, LBE2_n, LBE3_n, LD, LW_R_n signals are guaranteed setup at least 2 (LCLK/FPGA_CLK) clock cycles before signal ADS_n goes active. These signals are also guaranteed to be held active a minimum of 2 clock cycles after Readyn goes active. Also Rdyack_n will not pulse active sooner than 2 (LCLK/FPGA_CLK) clock cycles after Readyn goes active.

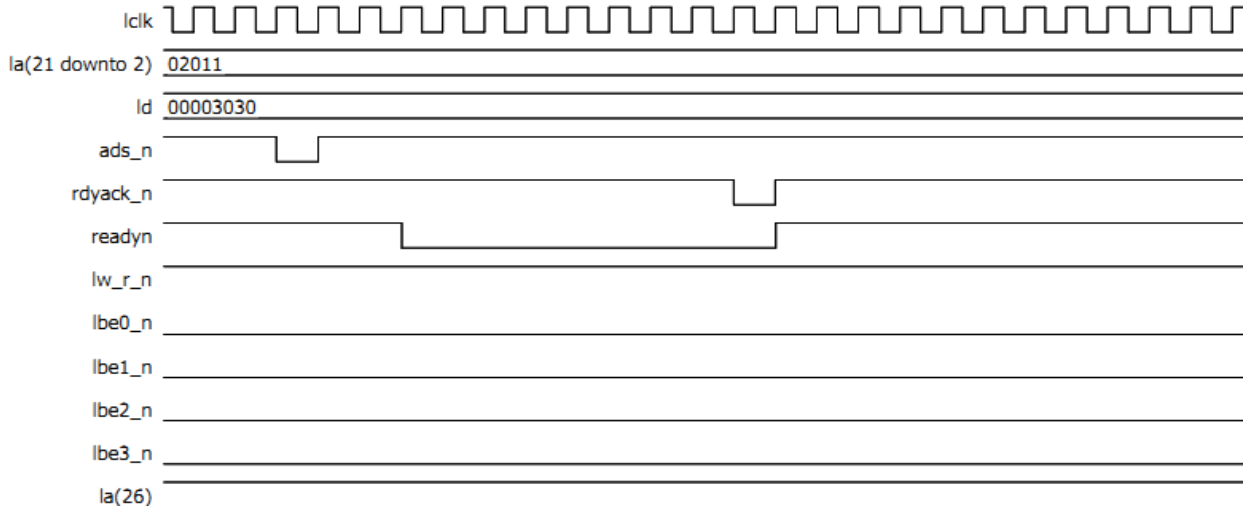

Both LCLK and FPGA_CLK are driven by the same zero delay Cypress clock driver. Signal ADS_n is driven by an OLogic register using the LCK at the bus interface FPGA. ADS_n is received at the programmable FPGA using FPGA_CLK at an ILogic register. This interface is considered synchronous to the LCLK/FPGA_CLK by Acromag.

Local Bus CLOCK CONTROL

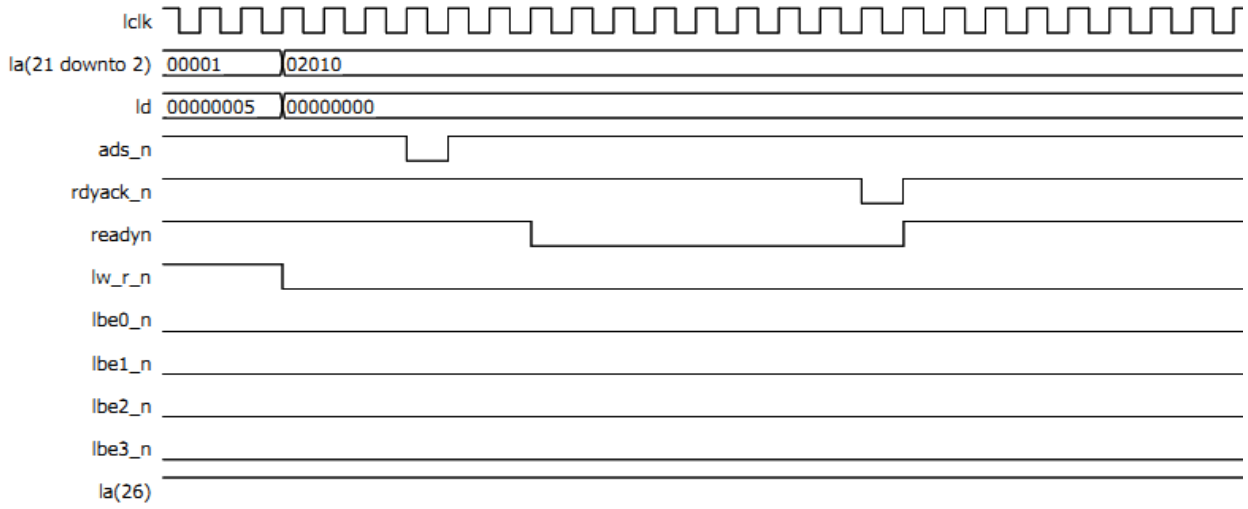

Clk, the local bus clock, as seen in the following timing diagrams can be one of two sources. By default clk is a Digital Clock Manager (DCM) generated clock frequency. Clk can also be selected directly from the board 125MHz frequency.

The Local bus clk signal is controlled by USERo. The board clock is routed to the Dual Port SRAM and user-programmable FPGA (U7) using a low skew clock driver (Cypress CY23EP05). The on board 125MHz crystal oscillator is input to the user-programmable FPGA via signal FPGA_CLK_PLL. After the user-programmable FPGA (U7) is configured, an FPGA DCM generated clock signal (PLL_CLK) is selected as the board clock (the default condition). By setting bit-8 of the Software Reset and Status register, at BAR2 plus 8000H, to a logic high the 125MHz clock may be selected as the board clock. By setting bit-8 to a logic low the PLL_CLK becomes the board clock frequency. The default state of bit-8 is logic low.

5.0 SERVICE AND REPAIR

Surface-Mounted Technology (SMT) boards are generally difficult to repair. It is highly recommended that a non-functioning board be returned to Acromag for repair. The board can be easily damaged unless special SMT repair and service tools are used. Further, Acromag has automated test equipment that thoroughly checks the performance of each board. When a board is first produced and when any repair is made, it is tested, placed in a burn-in room at elevated temperature, and retested before shipment.

SERVICE AND REPAIR ASSISTANCE

Please refer to Acromag's Service Policy Bulletin or contact Acromag for complete details on how to obtain parts and repair.

PRELIMINARY SERVICE PROCEDURE

Before beginning repair, be sure that all of the procedures in Section 2, Preparation For Use, have been followed. Also, refer to the documentation of your carrier/CPU board to verify that it is correctly configured. Replacement of the board with one that is known to work correctly is a good technique to isolate a faulty board.

CAUTION: POWER MUST BE TURNED OFF BEFORE REMOVING OR INSERTING BOARDS

If you continue to have problems, your next step should be to visit the Acromag worldwide web site at http://www.acromag.com. Our web site contains the most up-to-date product and software information.

WHERE TO GET HELP

Acromag's application engineers can also be contacted directly via telephone or via email for technical assistance through the number or email address listed at the bottom of this page. When needed, complete repair services are also available.

6.0 SPECIFICATIONS

PHYSICAL

Single XMC Board

Height	13.5 mm (0.531 in)
Stacking Height	10.0 mm (0.394 in)
Depth	149.0 mm (5.866 in)
Width	74.0 mm (2.913 in)
Board Thickness	2.21 mm (0.08 in)

Unit Weight

XMC-VLX: 3.59oz (0.1016Kg), typical

Connectors

- **P15** XMC.3 144-pin Samtec ASP-103614-05 connector Complies with ANSI/VITA 42.3-2006
- **P14** Rear I/O Interface: One 64-pin female receptacle header (AMP 120527-1 or equivalent). This connector provide 64 rear I/O connections.

- Front Field I/O Connector on XMC module (Samtec QSS-075-01-L-D-A) Mating Mezzanine Connector (Samtec QTS-075-01-L-D-A) with 5mm stack height or (Samtec QTS-075-02-L-D-A) with 8mm stack height.

Power Requirements		XMC Modules
VPWR 12V (±5%)	Typical	820mA
	Max.	984mA
3.3V (±5%)	Typical	700mA
	Max.	840mA

Table 6.1: Power Requirements for Example Design. Power will vary dependent on the application.

5V Maximum rise time of 100m seconds

On Board 1.0V Power to Virtex-5 FPGA	Current Rating (Maximum available for the user-programmable FPGA)
1.0V (±5%)	4A Maximum

ENVIRONMENTAL

Operating Temperature: 0 to +70°C. –40°C to +85°C (E Version)
Conduction Cooled XMC mezzanine card: Complies with ANSI/VITA 20-2001 (R2005). The XMC VLX, without a faceplate, is fully compatible with a conduction cooled host card.
Relative Humidity: 5-95% Non-Condensing.
Storage Temperature: -55°C to 125°C.
Non-Isolated: Logic and field commons have a direct electrical connection.

Radiated Field Immunity (RFI): Complies with EN61000-4-3 (3V/m, 80 to 1000MHz AM & 900MHz. keyed) and European Norm EN50082-1 with no register upsets.

Conducted R F Immunity (CRFI): Complies with EN61000-4-6 (3V/rms, 150KHz to 80MHz) and European Norm EN50082-1 with no register upsets.

Surge Immunity: Not required for signal I/O per European Norm EN50082-1.

Electric Fast Transient (EFT) Immunity: Complies with EN61000-4-4 Level 2 (0.5KV at field I/O terminals) and European Norm EN50082-1.

Electrostatic Discharge (ESD) Immunity: Complies with EN61000-4-2 Level 3 (8KV enclosure port air discharge) Level 2 (4KV enclosure port contact discharge).

Radiated Emissions: Meets or exceeds European Norm EN50081-1 Pre-Compliance for class B equipment. Shielded cable with I/O connections in shielded enclosure are required to meet compliance.

FPGA (XMC-VLX85)

Xilinx XC5VLX85T-1FF1136

- 51,840 CLB Flip Flops
- 840,000 Distributed RAM Bits
- 216 18Kbit Block RAMs
- 48 DSP Slices
- 6 Clock Management Tiles

FPGA (XMC-VLX110)

Xilinx XC5VLX110T-1FF1136

- 69,120 CLB Flip Flops
- 1,120,000 Distributed RAM Bits
- 296 18Kbit Block RAMs
- 64 DSP Slices
- 6 Clock Management Tiles

FPGA (XMC-VLX155)

Xilinx XC5VLX155T-1FF1136

- 97,280 CLB Flip Flops
- 1,640,000 Distributed RAM Bits
- 424 18Kbit Block RAMs
- 128 DSP Slices
- 6 Clock Management Tiles

REAR I/O

The rear I/O P4 XMC connector connects directly to banks 1, 4 and 21 of the FPGA. The bank 1, 4 and 21 Vcco pins are powered by 2.5 volts and thus will support the 2.5 volt IOStandards. Table 6-39 of the Virtex 5 User Guide (available from Xilinx) lists all the supported IOStandards available. The example design defines the rear I/O with 2.5 volt LVDS.

- Maximum Recommended Clock Rate…….150MHz (6.7ns clock period)
- Vcco Supply Voltage ……..…..…2.5 volt
- V_{OH} Output High Voltage……..1.602 volt
- V_{OL} Output Low Voltage……..….0.898 volt
- V_{ODIFF} Differential Output Voltage ……..…350m volt typical
- V_{OCM} Output Common Mode Voltage…...1.25 volt typical
- V_{IDIFF} Differential Input Voltage……..100m volt minimum
- V_{ICM} Input Common Mode Voltage…….0.3 volt min, 1.2 volt typical, 2.2 volt max

FRONT I/O

See the mezzanine module users manual for front I/O specifications. This PMC module uses the 150 pin Samtec connector part number QSS-075-01-L-D-A which mates with the mezzanine module connector part number QTS-075-02-L-D-A-K

Write Disable Jumper

Write Disable Jumper: Removal of surface mount resistor R172 disables write to the to the Xilinx FPGA configuration flash device. The location of R172 is shown in diagram 4502-088.

Board Crystal Oscillator: 125MHz
Frequency Stability: ± 0.0020% or 20ppm

Double Data Rate 2 SDRAM

32M x 32-bit Density
Micron MT47H32M16CC

SDRAM Crystal Oscillator: 200MHz
Frequency Stability: ± 0.01% or 100ppm

DDR SDRAM Clock: 125MHz
Data Transfer Rate: 250M longwords(32-bits)/s

Dual Port SRAM

1Meg x 64-bit Integrated Devices Technology IDT70T3509MS133BP, 133 Megahertz Speed

Flash Memory

16M x 8-bit 128 addressable sectors of which 41 are used for FPGA Configuration

PCIe Bus Interface

PCI Express 1.1: PCI Express electrical and protocol standards. Performs 2.5 Gbps data rate per lane and per direction.

ANSI/VITA 42.0: Complies with XMC module mechanicals and connectors

ANSI/VITA 42.3: XMC module with PCI Express Interface

4K Memory Space Required (BAR0): 64 bit Base Address Register 0 for access to configuration registers

4M Memory Space Required (BAR2): 64 bit Base Address Register 2 for access to the user-programmable FPGA (U7).

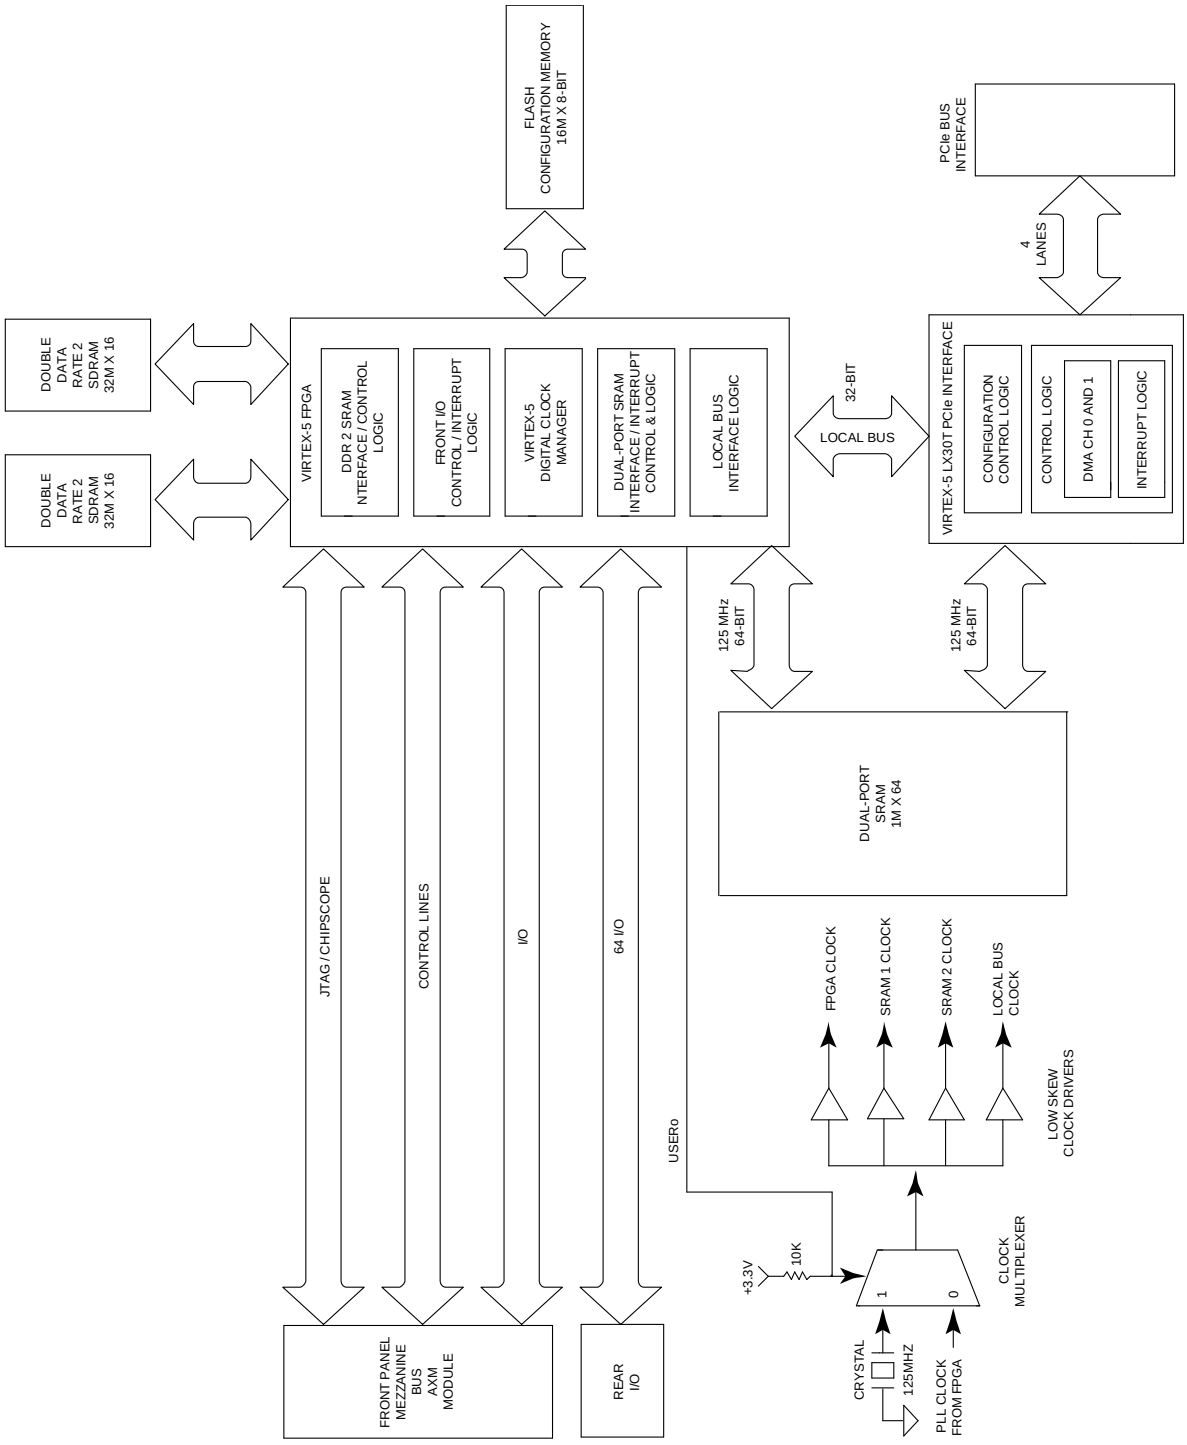

8M Memory Space Required (BAR4): 64 bit Base Address Register 1 for access to Dual Port SRAM.

Interrupts: Source of interrupt can be from the U7 programmable FPGA, or DMA Channels.

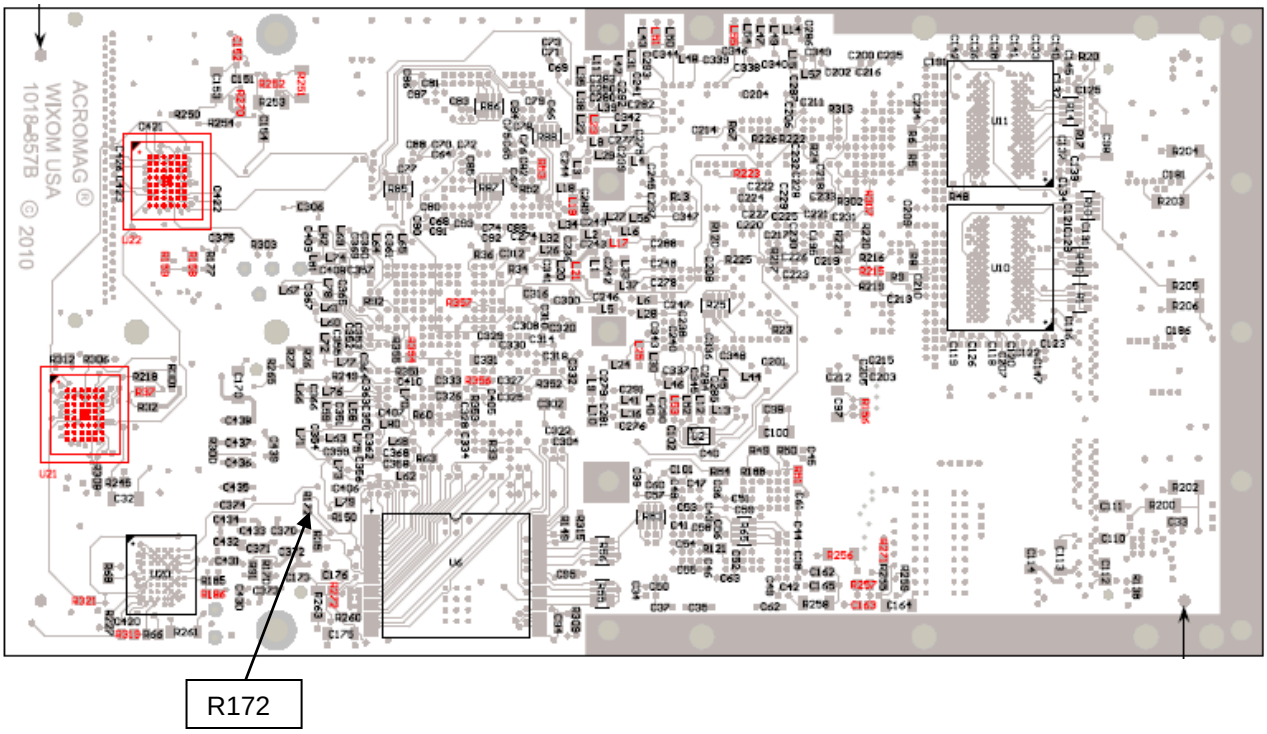

Certificate of Volatility				
Acromag Model XMC-VLX85(E) XMC-VLX110(E) XMC-VLX155(E)	Manufacturer: Acromag, Inc. 30765 Wixom Rd Wixom, MI 48393			
Volatile Memory				
Does this product contain Volatile memory (i.e. Memory of whose contents are lost when power is removed) ■ Yes □ No				
Type (SRAM, SDRAM, etc.) SRAM	Size: 1Meg x 72	User Modifiable ■ Yes □ No	Function: Data storage for FPGA	Process to Sanitize: Power Down
Type (SRAM, SDRAM, etc.) FPGA based RAM	Size: Variable up to 1.28Mbyte	User Modifiable ■ Yes □ No	Function: Data storage for FPGA	Process to Sanitize: Power Down
Type (SRAM, SDRAM, etc.) SDRAM	Size: 32M x 32	User Modifiable ■ Yes □ No	Function: Data storage for FPGA	Process to Sanitize: Power Down
Non-Volatile Memory				
Does this product contain Non-Volatile memory (i.e. Memory of whose contents is retained when power is removed) ■ Yes □ No				
Type(EEPROM, Flash, etc.) Flash	Size: 16Mbyte	User Modifiable ■ Yes □ No	Function: Storage of Code for FPGA	Process to Sanitize: Clear Flash memory by writing a logic 1 to bit-0 of the Flash Erase Chip Register at BAR2 + 24H
Type(EEPROM, Flash, etc.) Flash	Size: 32Mbit	User Modifiable □ Yes ■ No	Function: Storage of Code for PCIe bus Interface Device	Process to Sanitize: Not Applicable
Type(EEPROM, Flash, etc.) EEPROM	Size: 2kbit	User Modifiable □ Yes ■ No	Function: IMPI - FRU information	Process to Sanitize: Not Applicable
