Definitions

All specifications and characteristics apply over a 25 °C ±5 °C range (unless otherwise stated) and 90 minutes after the instrument has been turned on.

Specification (spec.): Warranted performance. Specifications include guardbands to account for the expected statistical performance distribution, measurement uncertainties, and changes in performance due to environmental conditions.

Characteristic (char.): A performance parameter that the product is expected to meet before it leaves the factory, but that is not verified in the field and is not covered by the product warranty. A characteristic includes the same guardbands as a specification.

Typical (typ.): Expected performance of an average unit which does not include guardbands. It is not covered by the product warranty.

Nominal (nom.): A general, descriptive term that does not imply a level of performance. It is not covered by the product warranty.

Calibration: The process of measuring known standards to characterize a network analyzer's systematic (repeatable) errors.

Corrected (residual): Indicates performance after error correction (calibration). It is determined by the quality of calibration standards and how well "known" they are, plus system repeatability, stability, and noise.

Uncorrected (raw): Indicates instrument performance without error correction. The uncorrected performance affects the stability of a calibration.

Standard: When referring to the analyzer, this includes no options unless noted otherwise.

Corrected System Performance

The specifications in this section apply for measurements made with the E8361A/C analyzer with the following conditions:

- 10 Hz IF bandwidth
- No averaging applied to data

[a] The system dynamic range is calculated as the difference between the noise floor and the source maximum output power. System Dynamic Range is a specification when the source is set to Port 1, and a characteristic when the source is set to Port 2. The effective dynamic range must take measurement uncertainties and interfering signals into account as well as the insertion loss resulting from a thru cable connected between Port 1 and Port 2..

[b] The test port system dynamic range is calculated as the difference between the test port noise floor and the source maximum output power. The effective dynamic range must take measurement uncertainties and interfering signals into account as well as the insertion loss resulting from a thru cable connected between Port 1 and Port 2..

[c] The direct receiver access input system dynamic range is calculated as the difference between the receiver access input noise floor and the source maximum output power. The effective dynamic range must take measurement uncertainties and interfering signals into account. This set-up should only be used when the receiver input will never exceed its damage level. When the analyzer is in segment sweep mode, the analyzer can have predefined frequency segments which will output a higher power level when the extended dynamic range is required (i.e. devices with high insertion loss), and reduced power when receiver damage may occur (i.e. devices with low insertion loss). The extended range is only available in one-path transmission measurements.

[d] Typical performance.

[e] May be limited to 100 dB at particular frequencies below 500 MHz due to spurious receiver residuals. Methods are available to regain the full dynamic range.

Note: This E8361A/C document does NOT provide technical specifications for Receiver Dynamic Range.

Note: This E8361A/C document provides technical specifications for the following calibration kits and Ecal modules only: 85056A, 85058B, N4693A, N4694A. Please download our free Uncertainty Calculator from http://www.keysight.com/find/na_calculator to generate the curves for your PNA setup.

[a] Specifications apply over environment temperature of 23°C +/- 3°C, with less than 1°C deviation from the calibration temperature.

[b] Typical performance.

[c]Transmission tracking performance noted here is normalized to the insertion loss characteristics of the cable used so that the indicated performance is independent of the cable used.

[d] Measurement conditions: normalized to a thru, measured with two shorts, 10 Hz IF bandwidth, averaging factor of 16, alternate mode, source power set to the lesser of the maximum power out or the maximum receiver power.

[e] 0 Hz offset.

[a] Test port output is a specification when the source is set to Port 1, and a characteristic when the source is set to Port 2.

[b] Typical performance.

[c] Preset power.

[d] Power Level Linearity is a specification when the source is set to Port 1, and a typical when the source is set to Port 2.

[e] Test port power is specified into nominal 50 ohms.

[f] Power to which the source can be set and phase lock is assured.

[g] +/-1.6 dB for power>-5 dBm.

[h] Assumes no variation in time.

[i] Assumes no variation in temperature.

[1] Total average (rms) noise power calculated as the mean value of a linear magnitude trace expressed in dBm.

[2] Typical performance.

[3] Noise floor may be degraded by 10 dB at particular frequencies (multiples of 5 MHz) due to spurious receiver residuals.

[4] Specified value is for worst-case noise floor at 45 MHz

[5] 0 Hz offset

[6] Coupler roll-off will reduce compression below 500 MHz. Ultimately, at 45 MHz, compression is negligible.

[7] Specified value is for worst-case compression at 500 MHz.

[8] This compression level comes from the dynamic accuracy curve with -30 dBm reference test port power.

[9] Option 016 degrades performance by 3 dB.

[10] TOI is a typical specification that applies while the network analyzer receiver is in its linear range.

[11] Trace noise magnitude may be degraded to 20 mdB rms at harmonic frequencies of the first IF (8.33 MHz) below 80 MHz.

[12] Stability is defined as a ratio measurement made at the test port.

[a] Dynamic accuracy is verified with the following measurements:

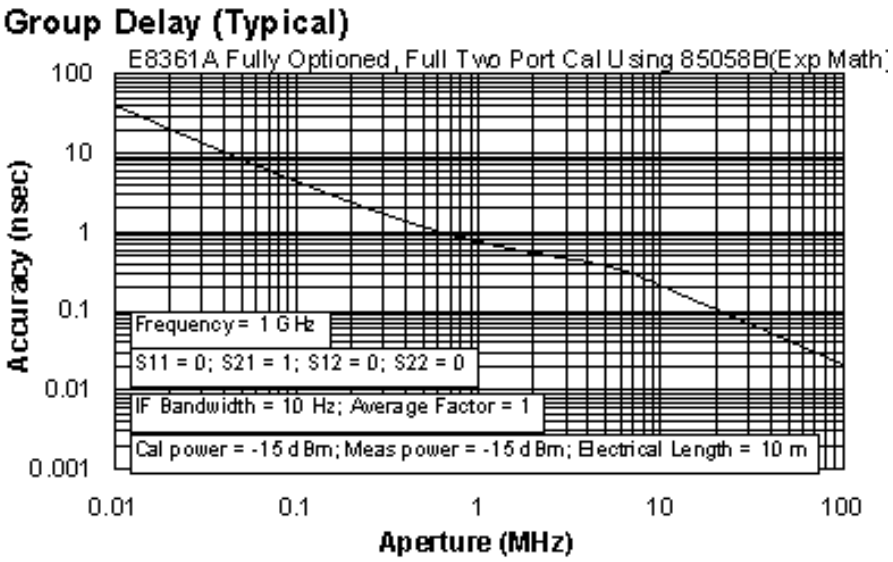

- compression over frequency
- IF linearity at a single frequency of 1.195 GHz and a reference level of -20 dBm for an input power range of 0 to -120 dBm.

Table 14. **Test Port Input (Group Delay)**[a]

Description	Specification	Supplemental Information (typ.)
Aperture (selectable)	--	(frequency span)/(number of points - 1)
Maximum Aperture	--	20% of frequency span
Range	--	0.5 x (1/minimum aperture)
Maximum Delay	--	Limited to measuring no more than 180° of phase change within the minimum aperture.)
Accuracy	--	See graph below. Char.

The following graph shows characteristic group delay accuracy with full 2-port calibration and a 10 Hz IF bandwidth. Insertion loss is assumed to be < 2 dB and electrical length to be ten meters.

NOTE: The following graph also applies to the "C" model of the analyzer.

In general, the following formula can be used to determine the accuracy, in seconds, of specific group delay measurement:

±Phase Accuracy (deg)/[360 × Aperture (Hz)]

Depending on the aperture and device length, the phase accuracy used is either incremental phase accuracy or worst case phase accuracy.

[a] Group delay is computed by measuring the phase change within a specified frequency step (determined by the frequency span and the number of points per sweep).

[1] Pulse input connectors are operational only with Option H08 (Pulse Measurement Capability) enabled.

[2] Based on deviation from signal reduction equation: Signal Reduction (dB) = $20\log_{10}$(Duty_cycle) = $20\log_{10}$(pulse_width/period). Measured at Pulse Repetition Frequency (PFR) of 1 MHz.

[3] Test port power has to be at a high enough level such that the “Drop Cal” does not occur. If Drop Cal occurs then the power out of the rear panel RF connector will drop by about 15 dB.

[3] A third-wire ground is required.
